OVERSEAS INFORMATION SERVICES

THE question whether the overseas services of the British Broadcasting Corporation should continue to be grouped with broadcasting in the United Kingdom, and with television, as the monopoly of a single corporation, was placed by the Beveridge Committee as the second of the fundamental issues it was asked to resolve. Nevertheless, overseas broadcasting was manifestly regarded as a secondary issue by the Committee, and its comments have received little attention. Mr. John Coatman has argued cogently for placing the overseas services under organizations in appropriate relation with the British Broadcasting Corporation, and for restoring the Corporation to its old position as the broadcasting authority for the people of the United Kingdom alone. Since overseas broadcasting was intended to be a projection, not of the government of the day in Britain, but of Britain and of the nature of the British way of life and liberty, the Beveridge Committee admitted that overseas broadcasting should be a function of some body independent of the Government, but was not prepared to recommend division or devolution. It recommended instead continuance of the existing arrangements for division of responsibility for overseas broadcasting between the government and the British Broadcasting Corporation, and this recommendation was accepted by the Government in a White Paper issued last May.

The cost of the overseas services of the B.B.C. will thus continue to be borne by a grant-in-aid from the Exchequer, and the cost will be calculated as the definable additional expenditure incurred on account of the overseas services. This arrangement does not, however, meet one important criticism made by the Beveridge Committee, the report of which directed attention to the different line taken by the Government in fixing the deduction to be made by the Post Office from gross licence revenue to cover the costs of collecting the fees and of the interference service. The Post Office includes in those costs a share of the total overheads of the Post Office, a practice for which there is every justification in view of the liability of the discharge of the proper and normal functions of the Post Office to be obstructed by the multifarious duties it undertakes for other Departments of State. The Beveridge Committee was unanimous that the charge made by the Corporation to the Government for overseas services should in future be calculated on the same principles and include overheads.

The silence of the White Paper on this point, coupled with the dubious honesty, to say the least, of the fifteen per cent deduction from the net licence revenue, gives point to the Beveridge Committee's remark that in the financial arrangements for overseas broadcasting the Government has been attempting to obtain benefits without paying for them. On this parsimony and its consequences the Ninth Report from the Select Committee on Estimates* turns a searching light, and the Government emerges from this scrutiny with little credit. The Estimates Committee has grave doubts whether the present procedure is any longer an appropriate method of ensuring, on one hand, that the Corporation has the necessary freedom to carry out its task, and on the other that Parliament has the requisite control over the directions in which public money is spent.

---

* Ninth Report of the Select Committee on Estimates. Session 1951–52. Overseas Broadcasting. Pp. xxvii+146. (London: H.M.S.O., 1952.) 6s. 6d. net.

When the B.B.C. was designated as the chosen instrument for broadcasting overseas, the government was anxious that the freedom of the Corporation should be curtailed as little as possible. This was fully appreciated by the Beveridge Committee, and was one reason for its recommending the continuance of the existing arrangement. The Estimates Committee, however, is now convinced that the real control exercised by Departments of State, especially the Foreign Office, the Service Departments and the Colonial Office, has considerably increased. With such increased departmental influence, closer Parliamentary control must obviously be exercised.

It must be borne in mind in considering this report from the Estimates Committee that its functions are limited to the examination of the estimates, and to reporting on the form in which they should be presented or on possible economies. Nevertheless, the Select Committee has taken a wide view of its responsibilities, and its outspoken comments may do something to stimulate action to remedy the damage already caused by short-sighted parsimony.

Virtually the sole income of the British Broadcasting Corporation for its overseas services is the grant-in-aid, amounting to £4,750,000. The overseas programmes of the Corporation are sent to countries and in languages prescribed by government departments through the Postmaster-General. They include the General Overseas Service broadcast entirely in English and designed primarily for British communities abroad, including troops stationed overseas, and for the Commonwealth and Empire, and two main groups: the European Services and the Overseas Services, the latter comprising the North and Latin American, Eastern, Far Eastern, Pacific and South African and Colonial Services. The transcription studios in London provide a universal service of transcriptions in English running to six hundred programmes a year. The value of this service lies in the furtherance of the purpose of 'projecting Britain'. But to obtain the full value of the service the Corporation believes a local representative is needed; withdrawal of the Corporation's officers from South America is expected to result in a considerable curtailment of the use of B.B.C. recordings there.

Besides this, the 'external' services of the B.B.C. include the 'monitoring' service, developed in wartime, of listening to and reporting on the broadcasting services of other countries. Although carefully co-ordinated with the Americans, this monitoring service, to which the powers of prescription have been extended by the new licence, has a staff of 572, out of the 3,307 employed by the external services, and is estimated to cost £454,000; nor does there appear to be any prospect of reduction here.

The parsimony of the Government outlook, however, is shown by the unrealistic hope of the Treasury, in spite of the evidence of this report, that economies in overheads will avoid the need for a supplementary estimate. To this attitude the Estimates Committee in its examination of the purpose of external broadcasting supplies a wholesome and much needed corrective. It notes, naturally, the general lowering of morale resulting from successive cuts in the grant and consequent reduction in staff, as well as the resignations of foreign staff and increasing difficulty in recruiting suitable staff from abroad. It emphasizes the long-term character of broadcasting to other countries. A reputation for objectivity is only built up over a period of years, and once a service is abandoned it is difficult to restore. Wave-lengths unused, even for part of a day, are quickly snapped up by other broadcasters. Thus the Committee cites the abandonment of the Latin American services over the past two years.

In this connexion the Estimates Committee expresses surprise that the Board of Trade is not a prescribing department. Manifestly, British overseas trade must play a major part in providing the resources necessary to win the 'cold war', and this depends largely upon prestige. Broadcasting is directed to peoples, not to governments, and in the free world it is the peoples far more than governments that buy. It is thus not enough for the Board of Trade to be represented in regard to overseas broadcasting by the Foreign Office; and one of the Estimates Committee's most important recommendations is that the Board of Trade should be more closely associated with the external services and should be designated as one of the prescribing departments.

The Estimates Committee rightly observes that the influence of broadcasting on backward peoples is potentially great, and that the Colonies are likely to continue to rely to a large extent upon the services offered by the Corporation. "In fact," it is remarked, "broadcasting has become one of the main links of the Commonwealth." But it is not the only link, and the expenditure on broadcasting for such purposes needs to be reviewed in the light of other expenditure directed towards the same end, whether in the field of education or in other ways.

What is obviously required is a wider outlook than has characterized either the present Government or its predecessor. There must clearly be, as the Select Committee rightly indicates, a continuing watch over all such external services, to ensure that no service once instituted is allowed to run on after its marginal usefulness in the national interest has passed; but such a scrutiny must be informed by clear conceptions of what overseas broadcasting can contribute to the maintenance of British needs and interests, and by accurate knowledge of what is being done by other agencies in influencing the minds of peoples. It has, in fact, to take account of what is being done not merely by the British Council and the Colonial Office in the field of overseas education, but also of the work of bodies such as the United Nations Educational, Scientific and Cultural Organization.

In all this, science is only one facet, but an important one; and scientific men should consider how closely they are affected, and in what ways they could assist the more efficient and effective projection of the mind of Britain and of her achievements in science, no less than in other matters of the mind, so as to promote international understanding and provide a firmer basis for world peace. The greater freedom of scientific intercourse, whether it be by the exchange of publications, or the interchange of visits between individuals or institutional staff, depends in part on such mutual understanding as overseas broadcasting is designed to encourage. Even in the free world, much remains to be done in the way of the removal of restrictions before travel between one country and another is as free as is desirable for the advance of science itself; and such barriers are unlikely to be removed purely by unilateral action.

The Estimates Committee's report also makes it manifest how closely this question bears on that of technical assistance to the under-developed areas. That point is argued more closely in an article, "Science and Foreign Policy", by E. M. Friedwald, in a recent issue of *Impact of Science on Society* (Paris: Unesco). Mr. Friedwald urges that scientific and technical assistance is likely to become a major element in international relations and a powerful instrument for promoting goodwill between nations. It can only be fully effective, however, when political obstacles have been removed by the appropriate means; in this work overseas broadcasting and agencies such as the British Council count for much.

What seems to follow, therefore, from this inquiry of the Select Committee on Estimates into overseas broadcasting is that some further measures, which it was not within the scope of that Committee to suggest, are required. It recommends a system of quinquennial grants for the overseas services of the B.B.C., in order to enable the Corporation to plan ahead for reasonable periods in providing what is essentially a long-term project. The administration of such a grant and the continuing scrutiny of the appropriateness of particular services to changing conditions may well call for the establishment of an independent body with a wide purview and responsibility, possibly analogous to the University Grants Committee, and competent to survey not merely the external services of the British Broadcasting Corporation but also other activities by which British ideals and institutions are made known to the world and British prestige is maintained. Such a body might, for example, not merely eliminate any overlap existing between the work of the British Council, the external services of the British Broadcasting Corporation and the work of the Central Office of Information; it might equally eliminate much of the ill-informed and sometimes carping criticism to which all these activities are frequently subject. It could help to bring to the work of the British Council a stability which that body no less than overseas broadcasting needs if its work is to be planned and co-ordinated reasonably.

The first step in that direction, however, would seem to be the institution of an investigation, as was suggested by Mr. John Coatman some eighteen months ago. Besides inquiring into the opportunities for achieving greater economy and efficiency in this field, on which it is estimated some £11,000,000 is at present expended annually, by co-ordinating the work of the B.B.C., the British Council and the Central Office of Information, Mr. Coatman suggested that such a committee should inquire into the desirability of relieving the B.B.C. of all responsibilities in connexion with the political warfare type of broadcasting by transferring it to an appropriate government department or agency. The safeguard to objective overseas broadcasting which such transfer would give is obvious, and Mr. Coatman argued the point more fully in a subsequent article in *Public Administration* (29, 160; 1951), in which he also developed further reasons for a third suggestion which he would have the proposed committee consider, namely, replacement of direct transmissions of certain overseas services by a transcription service of British Home Service programmes.

Under the federal system which Mr. Coatman proposes he believes that such transcriptions would truly represent the life and culture of the whole nation. Moreover, by broadcasting on the national services, better reception conditions would be secured as well as much larger audiences than are at present reached, while two more medium wave-lengths would be made available for home broadcasting. The small committee envisaged by Mr. Coatman as competent to examine and report on these questions should be competent to examine the wider issues, and conduct the continuing surveillance suggested above if it is eventually constituted a permanent body with appropriate powers. The Estimates Committee's report strongly supports the arguments already advanced by Mr. Coatman, and the inquiry suggested appears to be the first step necessary to ensure both economy and effectiveness in interpreting the mind of Britain to the world, with all the possibilities that such activities hold for the advance of science itself and for enabling science to make its full contribution to the growth of international understanding.

HEAVY WATER

Physical Properties and Analysis of Heavy Water

By Isidor Kirshenbaum. Edited by Harold C. Urey and George M. Murphy. (National Nuclear Energy Series, Manhattan Project Technical Section, Division 3, Vol. 4A.) Pp. xv+438. (London: McGraw-Hill Publishing Co., Ltd., 1951.) 45s.

THIS new volume of the National Nuclear Energy Series is devoted to a topic which is of importance to a growing number of research workers who are using non-radioactive isotopes in tracer investigations. Much has already been published on the physical properties and analysis of heavy water; but in earlier publications there is a measure of disagreement. The subject was studied in great detail during the Second World War, particularly by a team working at Columbia University, and it is this new material which constitutes the main part of the present volume. The author and editors have, however, avoided the disjointed effect which was apparent in some earlier volumes of the series. The subject has been treated as a whole, and a coherent review is given both of the work done during the War and of other work published in the open literature.

The first chapter, on the physical properties of heavy water, deals with determinations of such properties as specific gravity, the melting and boiling points, vapour pressure, viscosity and refractive index, and with thermodynamic data. All the more important precise determinations appearing in the literature are reviewed, and full experimental details of new work are given. The author then proceeds to a discussion of exchange reactions involving heavy water, commencing with the calculation of the equilibrium constant for the reaction $H_2O + HD \rightleftharpoons HDO + H_2$ and its experimental investigation. A similar treatment of exchange reactions involving ammonia and carbon dioxide follows.

The large section of the book on mass-spectrographic analysis falls into two parts, the first devoted mainly to instruments and general techniques of measurement, and the second to problems connected with the isotopic analysis of heavy water by the mass spectrograph. In both parts there is much that is new, and many techniques are described in great ail. These include both methods for decomposing to obtain hydrogen for analysis, and also ls for equilibrating water samples with or deuterium gas in the presence of a The ways of analysing water for the e content are also described.

ner methods have been applied from time analysing heavy water for its deuterium Of these the author has chosen those ng density determinations by means of a float alling drop, and the refractometric method, for iled discussion. The existing literature is ewed, and a good deal of very precise work done ng the War is described. These methods are cularly useful for detecting small variations in bundance of hydrogen and oxygen isotopes in ral waters. Results in this field, which are ibed in the last chapter, may be of great value y future hypothesis concerning variations in the ic ratio of terrestrial materials.

great value of this book lies in its critical h. The author and editors have themselves sely concerned with much of the outstandingly li perimental work described. Their many rel ts of technique, and the careful assessment of tl ults of their experiments and those of others, consti a major contribution to the subject.

H. J. EMELÉUS

A PHYSICIST LOOKS FORWARD

The Next Million Years

By Sir Charles Galton Darwin. Pp. 210. (London: Rupert Hart-Davis, Ltd., 1952.) 15s. net.

WHENEVER Sir Charles Darwin sets out to write, we know he will produce something both unusual and interesting, and in this book he has not disappointed us. He is looking forward. But unlike most of his predecessors in this kind of writing, he is not limiting himself to a period of a cent when people very much like ourselves will on developments with which we are famil have started: instead he is trying to long-range "average history" of the worlc

Instead of the classical cause-and-effe Sir Charles adopts the statistical methoc the laws of probability. He points out that of an individual human being are as un as the movements of an individual molecu in a containing vessel; but the average duced by an enormous number of molecu predicted with great accuracy because, as of chances becomes larger and larger, th any single event become less and less imp they tend to cancel out. In statistical dy says, an enormous superstructure can be confidence out of a foundation that migh be very narrow. Pursuing the analogy fi may, he thinks, reasonably hope to find law controlling those unpredictable molecu beings, if we can find internal conditions to the condition of being a conservative system, and external conditions analog containing vessel.

The latter presents the lesser difficulty taining vessel is the earth, about which know a great deal—probably enough forecasts. The internal conditions analogo of conservative dynamical systems are the and characteristics of human nature, and generalities seem to emerge which hold fc however widely individuals may devia properties and characteristics change, sufficiently large numbers of events only and on analogy with the past, Sir Charl that it will take about a million years have gone far enough to make man so dif what he is now that he will become a n He does not think that these changes expedited by some dictator or ruling hormones or eugenic methods such a speedily produced changes in domesticate such differentiation into specified types improbable by the fact that man is "w than "domesticated". The necessary rulin thinks, could never emerge. Man as a will always multiply up to the limit available food supplies, and in consequen greatly these may be increased, there persist a large starving marginal populat increasing scientific control natural selecti some significance as a factor in deter chances of living, and some physical d may well follow its elimination.

Our present political systems are li modified. Democracy lacks survival v state of parasitism on the community eng modern social conditions is impermanent the end the parasite destroys its host anc perishes: the process is likely to be hast concomitant reduction of the more intell being now driven to have few or no child be the non-parasitic communities that v and those that multiply most will domina by sheer numbers. For this reason the au that world agreement to control popul never be attained: an aggressor nation o never permit their people to restrict the and other nations that wished to survive to follow suit. Government would pos some "hero" who has sufficient sense to adapt himself to a society of dense population. Here intellect will count, but morality may not, since "in a highly competitive world, the sinner has many advantages over the saint". Desire for children there must be, however, or the increased population could not eventuate, and *Homo sapiens* may well change into *Homo paediphilus*. Man, however, is a thinking being, and the author discusses the potent effect of creeds on his life and action—using the word "creed" to denote the whole body of tenets derived from teachers the surrounding society and direct personal experience. He instances China, where the belief in ancestor worship imposes on each man the duty of leaving descendants to continue the practice. As the children of abler people are more likely to survive in a population where many are on the verge of starvation, the creed has a strongly eugenic effect. Rome, with a different creed, collapsed under the attacks of the barbarians, while China, equally attacked, after two generations has absorbed and assimilated its Mongol conquerors and continued its course unperturbed: its people now form one-fifth of the human race. But in the long run and over great periods of time, Sir Charles is sceptical about the permanent effects of creeds.

Space does not permit an adequate summary of the author's forecasts: his final picture is, as he admits, rather gloomy. He foresees a densely crowded world with a permanent starving margin, where the people, looking back regretfully on the prodigious stores of energy and other natural resources that we have so lavishly wasted, are compelled to a harder existence than ours and set a lower value on human life. Conditions of work will become more severe for the less efficient, and the only mitigation will be for the more intelligent. There will be more discontent, and no notable addition to the sum of human happiness. Periodically there will come better times, "Golden Ages"—probably the greatest of these will have been the nineteenth century. Civilization is unlikely to be ended by war; but there is the chance that some irresponsible individual might blow up the whole planet with a sufficiently large hydrogen bomb when the secret of making such potent instruments is discovered.

Given the premises, the conclusions follow logically. The premises assume a universe where events fall out as in statistical dynamics, without intervention by a Deity as postulated by the Christian religion: a universe without a plan.

It would be interesting to compare this forecast with some of its predecessors. H. G. Wells used the cause-and-effect method, and with his marvellous gift of extrapolation was able to predict changes which, apparently fantastic at the time, nevertheless came about later. His picture, too, like that of Sir Charles, is depressing. Both forecasts are immeasurably remote from the radiantly optimistic visions of the nineteenth-century writers such as Edward Bellamy, whose "Looking Backwards", with its blissfully happy people progressing onwards and upwards for ever, was accepted by even so realistic a Victorian as Sydney Webb—who once told me more than sixty years ago that that was what the world would be like when we got Socialism.

The book is extremely interesting, and it will serve a useful purpose if it leads politicians to look forward more than the usual five years, and to try thinking out the long-term result of their policies.

E. JOHN RUSSELL

ORGANIC CHEMISTRY OF PHOSPHORUS

Organophosphorus Compounds

By Prof. Gennady M. Kosolapoff. Pp. vii+376. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1950.) 60*s*. net.

FROM the early days of systematic organic chemistry, organic compounds of phosphorus have been the subject of considerable investigation. Beginning in the late 1860's, the eminent German chemist Michaelis devoted a long and illustrious lifetime to their study, and he and his school were responsible for laying the foundations of the chemistry of phosphorus compounds. There followed the classical researches of Arbuzov in Russia, and more recently British chemists have made outstanding contributions. The names of F. G. Mann and W. C. Davies are associated with valuable studies in the phosphine field, and to A. R. Todd we owe the development of several new methods of phosphorylation, elegant syntheses of substances related to nucleic acids, and notably the first authentic preparation of adenosine triphosphate.

Several organophosphorus compounds have to-day acquired industrial status for diverse applications as solvents, plasticizers, insecticides, surface-active agents, flame-proofing compositions, lubricating-oil additives and warfare agents. Schrader pioneered the use of phosphorus compounds as insecticides, and the discovery of systemic activity in certain derivatives has led to important developments. But undoubtedly the main interest in organophosphorus compounds derives from their biological significance. One need only mention the nucleic acids, phospholipids, phosphoproteins and amino-acids, various coenzymes, nucleotides, phosphorylated derivatives of sugars and the fact that two of the more recently discovered vitamins—vitamin B_{12} and pantothenic acid—seem to function biologically as phosphate derivatives, to realize the importance of phosphorus compounds in the manifestations of life phenomena. Yet it is not unusual to find but scant reference to the organic chemistry of phosphorus in standard text-books even to-day. The appearance of this first treatise on the subject in English is therefore particularly welcome.

The author, Prof. G. M. Kosolapoff, who is of Russian extraction, has been able to draw on the fund of valuable information available in the scientific literature of that country. For more than a decade he has himself carried out researches in this field, originating and improving syntheses of organophosphorus compounds. Written from the point of view of an organic chemist, the book is intended primarily for organic chemists. Its scope is strictly limited to a review of preparative methods for various types of phosphorus compounds with discussion of their general characteristics. The interesting subject of the naturally occurring phospholipids, for example, is considered outside the scope of the volume, and biochemists will regret that no attempt has been made to treat biochemical aspects. Even so, Prof. Kosolapoff has rendered a signal service to the chemical community by filling a significant gap in the literature.

A serious difficulty in compiling this book was the confusion arising from lack of a universally adopted system of nomenclature for phosphorus derivatives. In his classification of compounds into types the author has departed from current practice in some respects, and he has eliminated as far as possible specific names which have been needlessly perpetuated. The term 'phosphinic' acids (R_2P(O)OH) has been abandoned, the acids being regarded as derived from phosphoric and phosphorous acids by replacement of hydroxyl groups by the radicals. The use of 'chloro-phosphonate' has also been rejected in favour of chlorophosphate.

Each chapter follows a general pattern: a brief introductory statement about the class of compounds dealt with, followed by detailed consideration of preparative methods applicable to compounds of that type, discussion of their general characteristics, a compilation (up to January 1950) of known authentic compounds with their physical constants and mode of synthesis and, finally, all pertinent references. Individual compounds with properties not typical of the group are noted. To avoid ambiguity owing to the several systems of nomenclature now in common usage, the tabulations of known compounds are based on structural formulæ in progressive order of complexity. These take the place of a comprehensive index of names at the end of the book. While this feature has the merit of permanency, it makes it a little more difficult for the non-specialist to trace any specific compound.

Laboratory workers in this branch of chemistry will value this book not only as a source of information on synthetic methods but also as a complete dictionary of organophosphorus compounds. J. IDRIS JONES

ANTHROPOLOGICAL STUDIES OF ARAB LIFE

Birth and Childhood among the Arabs

Studies in a Muhammadan Village in Palestine. By Dr. Hilma Granqvist. Pp. 289. 1947. 25 Danish kr.

Child Problems among the Arabs

Studies in a Muhammadan Village in Palestine. By Dr. Hilma Granqvist. Pp. 336. 1950. 30 Danish kr. (Helsingfors: Söderström and Co.; Copenhagen: Einar Munksgaard.)

DR. HILMA GRANQVIST'S earlier two-volume work in English, "Marriage Conditions in a Palestinian Village" (Helsingfors: Academic Bookstore, 1931–35), aroused, and merited, quite unstinted praise. Its excellence from a methodological point of view, its manner of presentation and its penetrating thoroughness are repeated in the two books now under review. During 1925–31 she spent three years in Palestine for the purpose of attaining "an objective knowledge of the Arab people in order to help us to understand the culture of Bible times, and therewith the sources of Christianity". To achieve such an aim, she wisely decided to concentrate on a detailed study of a small community, that of the village of Artas, bordering the desert south of Bethlehem, in preference to a large-scale but less intensive survey of Muhammadan Arabs as a whole. She has succeeded in a brilliant fashion and has permanently enriched anthropological and sociological literature by revealing a microcosm of Arab—one might fairly say Semitic—values and sentiments that have persisted since the days of the Prophets and still endure. Specialists in other fields have suggested 'Eber or Heber as the eponym of both 'Hebrew' and 'Arab', and here is a mass of evidence for the supremacy of custom in the very area from which the two ancient peoples (now, alas, so deeply at odds with each other) have made their most profound impress on Western civilization. The emphasis that recent students have laid on institutional factors in the determination of culture seems nugatory when compared with this predominance of custom, and, to judge from the quality of Dr. Granqvist's field-work, her sympathetic insight into Arab life and ambitions has shown that she combines to an extraordinary degree the dual role of anthropologist and philanthropist.

"Birth and Childhood among the Arabs" does not follow the tenets of one contemporary psychological school in stressing early toilet habits as decisive in the formation of a child's personality. Dr. Granqvist's net is far more widely cast, but the draught of ethnographical fishes brought up by it is in no sense less miraculous. The main topics comprise pre-natal and post-natal observances, the paraphernalia of pregnancy and birth—how little significance, incidentally, does the caul seem to possess in Palestinian folk-belief—as well as nursing, children's games and work, education and the development of character and, finally, circumcision. It may be thought that Dr. Granqvist was particularly fortunate in choosing as her principal informant the blind widow Alya, and in securing the good offices of the daughter of the Alsatian missionary family of Baldensperger, resident in Artas since 1840, in whose house she lodged; but this would do scant justice to the erudition she herself brings to the treatment of her subject and the wealth of comparative material she cites from Biblical and other sources in support of her own findings. These confirm her contention that the possible influence exercised by the child on the religion and language of the Bible has been underestimated, and they put theologians and anthropologists alike in her debt.

The second volume, "Child Problems among the Arabs", moves from the sphere of custom and the artless to that of the largely, if not wholly, more sober one of genealogical data and statistics. Here, too, Dr. Granqvist displays an impressive grasp of method which will be the envy of those concerned with population studies, and it is difficult to evaluate the careful inferences she draws from her observations in other than superlative terms. The first chapter is devoted to an analysis of names. Teknonymy, a word introduced by Tylor to denote the calling of parents after their children, is restricted to the eldest son in the Near East, where the practice is known as *kunya*. Once more the whole subject is illuminated by abundant documentation from literary sources. The scope of the remaining parts of the book includes sex-ratio, fecundity and fertility, child mortality and the *dits* relating to it, the treatment of ailing children by therapeutic and supernatural means, the position of children in a patriarchal society, child–parent relationships, and the importance of the social and familial environment to a child's upbringing. An extensive bibliography, a list of Biblical parallels and a detailed index to both volumes complete the contents.

It may be remarked without exaggeration that Dr. Granqvist's researches establish a new standard in ethnographical technique. Seldom does one come across investigators so completely at ease with the minutiæ of their inquiry, and in the present instance the author has evidently profited from the previous studies she made of purely religious problems, which, together with her work on family life among the

Arabs ("Arabiskt Familjeliv" (Stockholm: Åhlen and Soners forlag, 1939)), were written in Swedish. In common with other Scandinavian scholars, the Finns have developed the recording of their indigenous folk-culture to an extent that, in its literary aspect, is unmatched elsewhere, except perhaps in Ireland. (On the situation in Great Britain it is better to maintain an embarrassed silence.) Dr. Granqvist has equalled her fellow-countrymen's achievement in the superb contribution she has made to the study of a culture alien to her own. J. C. Trevor

FOUNDATION OF GOOD ROADS AND RUNWAYS

Soil Mechanics for Road Engineers

(Department of Scientific and Industrial Research: Road Research Laboratory.) Pp. xxiv+541+90 plates. (London: H.M. Stationery Office, 1952.) 30s. net.

The work of the Soil Mechanics Section of the Road Research Laboratory can be followed by interested persons in the many excellent publications issued, for example, in its 'technical papers' on compaction, soil survey procedure and pavement design, or in its 'road notes' on frost and drought damage, to quote only a few. In the volume under notice, these appear to have been collected together and carefully edited to form the most authoritative book on soil mechanics for road engineers at present available.

The book gives a complete picture of the soil mechanics knowledge that might be of use to a road engineer, from soil identification and classification, mechanical and chemical testing, soil stabilization and compaction, on to the ultimate goal of pavement design, each chapter being supplied with adequate references for further information. There are particularly interesting chapters on the movement of soil moisture and the investigation of foundation failures.

Each paragraph of the book is numbered, and this would lead one to suppose a good deal of cross-referencing. In fact, virtually none exists, except in broadest terms, and this is one of the weaknesses of the book. Each chapter can almost stand on its own, and this has led to a certain amount of repetition. For example, in one of the final chapters on bearing capacity, shearing resistance, Coulomb's equation and Mohr circles are referred to as if they had not been previously mentioned, whereas, in fact, there is a very full chapter devoted to shear strength, after which it is gratuitous to be told that "granular soils are more capable of carrying load if they are confined than if they are not".

The chapter on consolidation more logically comes before that on shear strength: then the $\varphi = 0$ result for undrained shear tests becomes more understandable. Similarly, it would be more logical to treat bearing capacity before pavement design. These criticisms could be met easily by efficient cross-references.

It would have been helpful if, in the section on the determination of specific gravity, typical values for soils had been given. Later on, an implicit value of 2·65 is used indiscriminately for clays and sands alike.

The effect of pore water pressures on shear strength, although initially correctly stated, does not appear to have been fully understood. For example, in saying that "the greater the drainage attained during a test, the greater will be the shearing resistance", the effect of the decrease in pore water pressure which takes place during an undrained test on a dilating soil has been overlooked.

Each chapter has its introduction, telling what is going to be said in it, and a summary telling what has been said. This is convenient for a technical journal where a number of different topics are treated; but here it would appear unnecessary. Again, the nine pages at the front devoted to figure titles seem unnecessary.

The diagrams and photographs are of a high quality, and the book is well produced apart from numerous printing errors which ought to be corrected before the next edition appears. K. L. Nash

BIRDS OF GREENLAND

Grønlands Fugle (The Birds of Greenland)

Text by Finn Salomonsen; Plates by Gitz-Johansen. Part 3. Pp. 349–608+plates 37–52. (København: Ejnar Munksgaard, 1951.) 3 vols., 42 dollars; £14 15s. 0d. Map of Greenland, prepared for The Birds of Greenland by Geodetic Institute and Finn Salomonsen. 40 cm. × 60 cm., 10 Danish kr.

This is the final part of an interesting work (for Vols. 1 and 2 see *Nature*, 167, 744 (1951) and 169, 48 (1952), respectively) and deals with the auks, birds of prey, owls and passeres. There is some evidence that the great auk bred in south-east Greenland in the sixteenth century. According to Greenland chronicles of Bjørn Jonssøn, Lutra Clemens, an Icelander, on a voyage to Greenland between 1580 and 1596, landed at Gummborjarn's Skerries, north-east of Angmagssalik, and loaded his boat with great auks. At a much later period, during 1768–74, this bird was a regular visitor in small numbers to west Greenland, and Fabricius tells us that they were killed for food by the Greenlanders, and the Danish inhabitants made blankets out of the skins. The last bird to visit Greenland was killed at Disko Island in 1821. The little auk, in contradistinction to its large namesake, is reputed to be the most numerous bird in the world, and Dr. Finn Salomonsen quotes one authority who estimates that in the Scoresby Sound district alone there are five million pairs. All the large breeding colonies are in the north, and those in the south are much smaller, sometimes only a few pairs. When the auk comes ashore to breed, they are preyed on by foxes, glaucous gulls and gyr-falcons, to say nothing of the numbers netted by Greenlanders for winter food. When at sea they run the gauntlet of seals, fish, and even whales, according to Salomonsen. Nevertheless, in spite of all this, there does not appear to be any signs of the birds becoming reduced in numbers.

Of the three birds of prey breeding in Greenland, the most interesting is the gyr-falcon, a circumpolar species. In the heyday of falconry the white form of this bird was in great demand and was usually only in the possession of kings, or very important people. Actually, in the pursuit of game it had not the dash of the peregrine, and Dr. Salomonsen's notes on the food and manner of hunting of these two birds is of great interest. He remarks also that the gyr-falcon is easily driven away by a pair of long-tailed skuas, or a pair of ravens, which would not be the case with the peregrine. The classification of the gyr-falcon has always been a matter of dispute owing to the differences in colour, which fall into three phases—white, grey and dark. The author follows Schiøler and other Danish ornithologists, and divides the forms in Greenland into two races, *Falco r. candicans*, the white bird breeding in the north, and *F. r. obsoletus*, breeding in the sub-Arctic and low Arctic zones, and which may be either grey or dark in colour with many intermediate coloured birds.

Among the passeres, the field-fare calls for attention, since it first began to nest in Greenland in 1943 and is now a regular breeder; this is an interesting case of colonization. From the systematic list at the end of this part we learn that 224 species and subspecies have been recorded from Greenland, and, out of these, 64 breed regularly, 58 have only occurred once and most of the remainder are casual visitors.

There are a very good bibliography and map. It is to be hoped that Dr. Salomonsen will see his way to bring out in the near future a cheaper and smaller edition, without plates, of this important fauna.

N. B. KINNEAR

LIFE OF THE WESTERN ATLANTIC COAST

The Living Tide

By N. J. Berrill. Pp. xi+256+16 plates. (London: Victor Gollancz, Ltd., 1951.) 16*s*. 6*d*. net.

PROF. N. J. BERRILL'S excellent contribution to the ever-growing number of popular books about life in the sea is concerned mainly with the inshore life of the east coast of the United States. There are occasional excursions elsewhere, particularly to Salcombe and the coasts of Cornwall—scenes of the author's youth—but for the most part the theme is distinctly North American, though quite a number of the species described are common to both sides of the Atlantic. From Loggerhead Key in the Dry Tortugas northwards to Maine a number of outstanding examples of the marine flora and fauna are described with a bare minimum of technical words. The writing, never dull, presents a depth of sound biological knowledge in a light and entertaining manner that is wholly delightful. Especially noteworthy are the accounts of the breeding of the turtle, of the upside-down jellyfish *Cassiopeia* in the moat of Fort Jefferson, of *Limulus*, and of the skull and breeding of the crucifix fish (a species of cat-fish). There are first-rate chapters devoted to the lobsters, squids and seals of Maine.

It is a pity that Prof. Berrill, in his endeavour to eliminate all technicalities, leaves the biologist on the eastern side of the Atlantic to puzzle out the identity of some of the animals he mentions. There is need for an appendix giving the scientific equivalents of such popular appellations as the sea potato, the grey snapper, the blue crab, the quahog and the soft-shelled clam. The last-named, we are assured, is "sand-gaper" in an English fish-market. There are occasional lapses of style, as in the sentence about the fanning feet of the barnacle pulling in a handful of water and food; and there are occasional errors of fact, as in the statement that *Zostera* is a terrestrial grass which has invaded the sea. But to dwell on these rare slips would be to give a false impression of a most readable and accurately written book.

Compared with the text, the photographic illustrations are disappointing. Two of the pictures are from habitat groups in the New York Natural History Museum; but the fanciful captions may lead the unwary to assume that they are photographs from life (unless, indeed, the wires suspending the trigger-fish happen to be noticed). The remaining photographs are from life and are of very mixed quality. The best, a good one, is of living squids; a few photographs are not in proper focus and should not have been included.

D. P. WILSON

THE SUGARCANE

Botany of Sugarcane

By Dr. C. van Dillewijn. Pp. xxiii+371. (Waltham, Mass.: Chronica Botanica Co., 1952.) n.p.

THE author has produced this considerable volume for the best of reasons, namely, that he wanted to do so and because he felt that such a volume, which relates to a major tropical crop, if not overdue, would certainly be timely. In contrast to other works on the sugarcane, which have been mainly practical, technological, historical or economic in their conception and outlook, this book is what its title declares it to be: essentially a work of botany. In it, on the basis of a bibliography of some 617 titles, the author has produced an account of the sugarcane plant in all its phases of germination, growth, development and reproduction. As perhaps might be expected, the data available to the author are somewhat uneven: some aspects have been the subject of intensive research, while others have remained comparatively neglected, those aspects which stand in a close relation to agricultural or technological aspects being most amply documented. Thus photosynthesis occupies thirty-two pages, respiration less than four.

The first section is devoted to a detailed illustrated account of the morphology and anatomy of the stem, buds, leaves, inflorescence and roots, and the second to physiological aspects, including germination, tillering, growth, chemical composition, nutrition, water relations, photosynthesis and respiration. In a contemporary work it is perhaps surprising that the genetical and cytological aspects are not included, though a chapter is devoted to the evaluation of vegetative characters in the classification of varieties, while the part played by the introduction of new varieties in safeguarding the industry is fully recognized.

The author rightly considers that cane-growing should be treated as a science, and with due emphasis he directs attention to the fact that there is a great gap between the relatively low efficiency in the field and the high efficiency in the factory. This he attributes to lack of knowledge, to failure to make use of knowledge that is available, and to dependence on tradition, local opinion and empiricism rather than on knowledge of the botany of the sugarcane and the related principles of its cultivation. In the present volume an attempt is made to remedy these defects and to make available to workers in all countries a comprehensive work of reference. The author and his publishers are to be congratulated on their achievement, and the hope may perhaps be expressed that the Chronica Botanica Company will regard this present volume as but one of a series of monographs on the botany of important crop plants.

C. W. WARDLAW

Advanced Five-Figure Mathematical Tables

By C. Attwood. Pp. v+69. (London: Macmillan and Co., Ltd., 1951.) 4*s*. 6*d*. net.

THIS book is intended as a continuation of the same author's "Practical Five-Figure Mathematical Tables", published in 1948. The collection of tables provided, however, is complete in itself, but the material might well seem strange to anyone unacquainted with the more elementary volume.

The trigonometrical tables are expressed in decimals of a degree, rather than in the usual intervals of six minutes, and an alternative set is also available with arguments in radians. As before, with emphasis on interpolation, small-interval tables have been supplied for the critical ranges, where the method of mean proportional parts is no longer adequate.

The tables of hyperbolic functions, which follow, include the hyperbolic tangent, not normally featured in books of this kind. Very detailed exponential tables for both positive and negative arguments between 0 and ± 7·5 (which incidentally render the presence of logarithm tables unnecessary) are followed by tables of the factorial function for intervals of 0·001 in the range from 0 to 1. In these, the author uses the symbol $x\,!$, instead of the more classical $\Gamma(x + 1)$, for $\int_0^\infty e^{-t}t^x dt$, with consequent minor modifications in the recurrence formula.

The final tables should prove most useful, containing as they do complete elliptic integrals of both kinds (with k^2 as argument) and ordinates and areas of the normal probability curve. In conclusion, a very comprehensive set of explanatory notes and formulæ, together with several numerical examples illustrating the correct use of the tables, serve to complete a book which is well produced and clearly printed.

J. H. PEARCE

Selective Toxicity with Special Reference to Chemotherapy

By Prof. Adrien Albert. (Methuen's Monographs on Biochemical Subjects.) Pp. xii+228+5 plates. (London. Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1951.) 7*s*. 6*d*. net.

MESSRS. METHUEN'S "Monographs on Physical Subjects" have long provided the student of moderate means with authoritative and modestly priced treatments of subjects not generally well covered by the orthodox text-books, and it is gratifying to know that similar provision is now being made in biochemistry. It is significant of the progress made by biochemistry in recent years that what might have been the first in the new series, namely, the late Dr. N. U. Meldrum's "Cellular Physiology", actually appeared in a series of monographs on biological subjects, and the publication of a series of monographs on biochemical subjects is a fitting tribute to the mature status to which biochemistry has now attained.

In this volume, based on a series of lectures delivered at University College, London, in 1949, students of biology and chemistry, coming fresh from their respective trainings in fundamental science to the hybrid subject of selective toxicity, will find much food for thought. While the choice of material in places emphasizes Prof. Adrien Albert's personal research interests and points of view, illustrations are drawn from a wide range of fields as far removed from each other as selective herbicides and local anæsthetics. After defining selective toxicity and describing applications, Prof. Albert discusses physicochemical aspects with reference to drug-receptor interactions, the role of ionization in the acridine antiseptics, chelation and trace metals. Chemotherapy is then reviewed, and various pharmacological themes are adumbrated in the closing chapter.

Chemical Indicators

By Prof. O. Tomiček. Translated by A. R. Weir. Pp. x+258. (London: Butterworths Scientific Publications, Ltd., 1951.) 21*s*.

THE subject of chemical indicators is of interest to many workers in the fields of pure and applied chemistry and biology, and, since advances are steadily reported in all its branches, a modern treatment is always welcome. The present volume, by an authority in the field, should be valuable to many kinds of workers.

The treatment is modern, the general theory of acids and bases being used throughout, and the fundamental equations are clearly deduced and their use explained in such a way that they should be easily understood by non-specialists. This is an important feature, since a proper use of indicators depends on a knowledge of recent advances in the theory of electrolyte equilibria which are not easy to follow unless simply presented. The equations are illustrated by numerical examples, which aid in elucidating their meaning.

The book includes a full account of apparatus and experimental methods, is provided with useful tables, and is very complete, since it deals not only with acid-base indicators but also with oxidation-reduction indicators, adsorption indicators, and fluorescent indicators. Full references to the literature are given. In every way this is a most useful and attractive book, which may be warmly recommended.

Theoretical Aerodynamics

By Prof. L. M. Milne-Thomson. Second edition. Pp. xx+414. (London: Macmillan and Co., Ltd., 1952.) 40*s*. net.

A REVIEW of the first edition of this treatise appeared in *Nature* of May 8, 1948. The fact that a second edition has been called for so soon is evidence of public appreciation of the book and of the vitality of aeronautical science.

The second edition is substantially identical with the first, except for the very notable addition of a chapter, running to 51 pages, devoted to supersonic 'conical flows'. By a conical flow is meant one in which the velocity vector, pressure and temperature are all constant on each straight line through a fixed origin. Such flows lend themselves to theoretical treatment of a relatively simple nature and there are many useful applications, for example, to wings of 'delta' plan form which are now being used on some high-speed aircraft. The new chapter is a valuable and welcome addition to the book. Some eccentricities of nomenclature have been amended in this edition; but the treatment of the mechanics of flight and of stability remains as before and is too short to be adequate.

In spite of the substantial increase in the size of the book and of the notorious increase in costs in recent years, the price of the book has not been raised. The author and publisher are to be congratulated on producing a book which, from all points of view, is good value for money.

W. J. DUNCAN

BEHAVIOUR OF SOCIAL INSECTS

THE social insects have for a long time attracted the attention of biologists, and, undoubtedly, the epoch-making discoveries of Prof. K. von Frisch and his colleagues have led to a great revival of interest in these groups, more especially perhaps in the bees and ants. At the recent meeting of the British Association in Belfast a part of Section D (Zoology) devoted a day to papers and discussions on the behaviour of ants, bees and termites; it was unfortunate that wasps could not be included.

During the morning session, under the chairmanship of the president of the Section, Prof. A. D. Peacock, members considered certain aspects of the behaviour of ants and termites. The behaviour of honeybees was the subject of the afternoon session, when Prof. G. C. Varley took the chair.

Ants and Termites

In his paper, Dr. J. H. Sudd (University College, Dundee) described a number of experiments on the possibility of forming colonies of Pharaoh's ant (*Monomorium pharaonis*) with various numbers and proportions of queens, workers and pre-adults, and discussed the significance of these results in the spread of natural infestations of this ant, which has established itself in such places as kitchens and bakeries. High humidity and temperature, and darkness in the nest cell, are necessary for successful culture of colonies of this ant in the laboratory.

Wheeler thought that, in general, ants could found colonies in one of two ways. Most commonly a sexual couple or a fertilized queen left the parent colony and raised brood, thus forming the nucleus of a new colony. In other cases some kind of swarming took place in which a sexual couple together with a number of workers left the parent colony and founded a daughter colony. Wheeler considered that swarming was uncommon in temperate species. In *M. pharaonis*, which is probably a tropical species, there is no sign of swarming. Mating takes place in the nest; but experimental attempts to found new colonies with sexual forms alone have always failed. This is not, however, because queens will not feed themselves, nor because isolated queens refuse to lay eggs.

What is even more remarkable is that attempts to found colonies with a population of one or more queens and a number of workers have also failed, although eggs were laid and in some cases larvæ were produced. In order to found colonies in the laboratory both workers and young stages are necessary; but a queen is unnecessary and may even be harmful, since she appears to compete with the larvæ for the attention of the workers and tends to be 'ritually' fed at the expense of the larvæ. After a few hours, however, the queen is deserted and the larvæ receive more attention. Such feeding of the queen by workers appears to be a truly instinctive act, with a releasing mechanism, and to have a variable threshold. The lowest ratio of workers to pre-adults with which a colony has been founded successfully was forty workers to fifty-three pre-adults, of which twenty-one were pre-pupæ.

Trapping has indicated the probability that established colonies of this ant have a habit of wandering as a whole, or of dividing and then rejoining, and perhaps it is not legitimate to think of the population of an infested building as consisting of a number of discrete colonies.

It seems clear that the spread of infestation of *M. pharaonis* is not a simple matter. For example, although it is no doubt possible for this species to be disseminated in a cake, it would be necessary for quite a large number of worker ants and pre-adult stages to be present if the establishment of a colony in a new situation is to result.

Dr. D. M. Vowles (University of Oxford) considered the social structure of the ant colony in terms of the behaviour patterns of the individual ant. He described how workers of *Lasius niger* will carry their brood from a light into a dark area and said that, if one ant is made to retrieve too many larvæ, this activity ceases, although other activities do not. This can therefore be interpreted as exhaustion of the drive for brood retrieving. The method of handling the brood when retrieving it varies in different species—the inherited innate component differs. Furthermore, the method of handling individual larvæ and pupæ depends upon their size, shape and similar characteristics, the taxis component of instinctive behaviour allowing adequate adjustment. The releasing stimulus seems to depend on a combination of size, odour, solidity and the hunched shape of the anterior end of the larva.

In *Myrmica ruginodis* the foraging activity, both of the individual and of her colony, can be intensified by increasing the proportion of larvæ to workers in the colony. Increasing the number of pupæ does not result in any increase of foraging activity. There are two types of foraging activity, one for sugar, which takes place continuously and represents the individual ant's feeding activity, and the other for protein, which is stimulated by the presence of larvæ, but not pupæ, and is parental activity.

Food exchange between workers is an important factor in the integration of the colony. The results of Dr. Vowles's work with *Camponotus pennsylvanicus* suggest that, when adult ants appear to be begging for food, they are really seeking it anywhere that they can find it and will take it from the first available source. They have learned early in life that they can obtain it from other workers, and he said that, as a rule, food exchange is a question of a would-be donor finding a willing acceptor. The signal for regurgitation appears to be a touch on the mouthparts, and the antennæ of both donor and acceptor appear to be used during food exchange for finding and orientating the other ant's head. It is the donating, rather than the receiving, behavioural mechanism which has evolved in ants.

Dr. Vowles concluded by suggesting that ant behaviour is essentially parental and that nearly all the duties performed by workers could readily have been carried out by their solitary ancestors. During the evolution of social life, worker ants have had to lose certain behaviour patterns, such as those involved with courtship, mating and egg laying, which if present would tend to disrupt the social life of the colony. One must distinguish between sexual and parental behaviour; only the former has become suppressed in worker ants.

Mr. S. J. Holt (Nature Conservancy, Edinburgh) gave some details of his work in a Scottish forest on the quantitative assessment of the foraging activities of colonies of the wood ant, *Formica rufa*. From a nest a number of well-defined, branching tracks radiate, each of which terminates in a large pine tree up which the foragers climb in search of honeydew. Each individual ant usually, but not invariably, uses one particular track on her way to and from the nest, and the speed at which she walks and, therefore, the rate of foraging and the rate of flow of foragers from the nest vary with the temperature. If one sets up check points along a track, one finds that the number of foragers passing along the track decreases the farther one gets from the nest, and, although most of the ants (about 80 per cent) keep to the track, a certain number leave it at intervals and spread out to hunt in the areas between the radiating tracks.

By marking individual ants belonging to a particular isolated colony, Mr. Holt has been able to study the economy of their colony. Each forager carried at one time about 0·0019 gm. of honeydew or, if she was collecting insect food, a load weighing on an average 0·008 gm. Each forager on a good day brought home food equivalent to about half her own body-weight. *Formica rufa* is very fond of midges, and on those days when midges settle in numbers on the rowan trees, the foragers tend to desert the pines and go to the rowans instead.

Prof. J. E. Webb (University College, Ibadan) considered the swarming behaviour of termites as an adaptation to the particular type of social life adopted by this order of insects in comparison with that found in the higher social Hymenoptera. He pointed out that the termites differ from most social insects in that each colony has both a king and a queen. The 'swarming' in termites of winged males and females is a prelude to colony formation, during which the male requires not only to contact the female but also to remain in association with her throughout the hazardous period before the first chamber of the new nest is formed. The chances of survival of the termite pair are much less than those, for example, of single fertilized queen ants, and the fact that they survive at all would appear to be due largely to the complex pattern of behaviour that winged termites exhibit during the process of 'swarming'.

The male and female termites emerge from the nests in which they have been born in large and approximately equal numbers around dusk on the day following the first rains; thus there is a reasonable chance of mating occurring between individuals from different colonies, and, further, at this time the soil will be soft, thus permitting easy excavation, and will remain so long enough for the colony to become sufficiently large to regulate its own humidity conditions.

On first emerging, the male and female termites are positively phototactic and are attracted by, and fly towards, the brightest light. The females settle on the ground some distance from their parent nests and shed their wings. The males search for females, making short flights interspersed with periods of running in all directions on the ground, and do not generally shed their wings until they have found females. When a male finds a female, he caresses the hind part of her abdomen with his mouthparts and antennæ, and this stimulates her to run forward with the male following 'in tandem'. As soon as such contact has been established, the female becomes negatively phototactic and runs away from the light in search of a suitable site, where both she and her mate begin to excavate the first chamber of the new nest. Should the pair become separated, the female promptly stands still with her abdomen raised and flattened while the male runs in circles seeking her. When contact is re-established the male resumes his caresses, which once more stimulate the female to run forward.

Prof. Webb pointed out that with respect to their swarming behaviour the termites appear to be unique among social insects. He said that the behaviour pattern he had described for *Macrotermes nigeriensis* is essentially similar, except for minor details, to that of all other termites, and suggests that this behaviour during swarming is one of the basic characteristics of the Isoptera and may well be one of the important factors which has initiated development of the social habit within the group.

During the short discussion which followed these four papers, Dr. S. H. Skaife (South Africa) suggested that it would be more correct to speak of the 'mating flight' of termites rather than 'swarming', as this phenomenon is in no way comparable with the 'swarming' behaviour of honeybees. Prof. Webb replied that, while agreeing that these two phenomena are not comparable, he thought that the term 'swarming' is well understood when used for describing the mating behaviour of termites and ants.

Dr. Sudd asked whether antennal stimulation by one ant is important in inducing another ant to give food to it. Dr. Vowles replied that he is convinced that it is not and, on the contrary, that it rather appears that an ant which wishes to give up food stimulates another ant to receive this food by offering it to her. Dr. C. G. Butler remarked that this also appears to be true in the case of worker honeybees. Most of the rest of the discussion, in which various members took part, was concerned with an attempt to find an all-embracing definition of social life, but no definition that was acceptable to all was suggested.

Prof. Peacock closed the discussion with a few remarks, in the course of which he said that he was very interested to find that there is so much in common in the behaviour shown by the different species of social insects that had been discussed.

Honeybees

The opening paper in the afternoon session was given by Mr. C. R. Ribbands (Rothamsted Experimental Station) on new evidence concerning the language of honeybees, in which he discussed some of the recent work which he and his collaborators, Dr. H. Kalmus and Mr. H. L. Nixon, have completed. Since this work has been recently discussed in *Nature* (September 13, p. 438), it is not reported in detail in this article. Suffice it to say that their experiments have demonstrated that food transmission among the honeybees of each colony is the foundation of the division of labour, and also, since they have shown this to be the basis of individual colony odour, enables the bees of a colony to distinguish their comrades from strangers and thus to protect their hive.

Dr. C. G. Butler (Rothamsted) briefly described some of the observations of Mr. J. B. Free and himself on the guarding of their hives by worker honeybees. He said that honeybees do not guard the entrances of their hives unless their colonies have been disturbed in some way, such as by the presence of numbers of strange bees, and that they are much more inclined to become and remain alert at those times when little or no fresh food is being brought into their hives and, similarly, to give up guard duties on the advent of a honey-flow. Almost any bee will assume guard duties when necessary, and, should numbers of strange bees attempt to enter the hive of a really alert colony, mass fighting sometimes takes place and many bees are killed. In such cases both the owners of the hive and the intruders apparently regard the hive as their own and attempt to defend it. However, such mass fighting between guard bees seldom occurs unless beekeepers are careless, and the fate of bees which attempt to enter hives which they have mistaken for their own is largely dependent on their own behaviour.

Guard bees recognize members of their own colony, as well as intruders from other colonies, by the scent of their bodies; but there is evidence that robber bees are recognized as such by their characteristic hesitant flight in front of the hive entrance before the guards can approach them closely enough to identify them by their scent. Guards always attempt to kill robber bees, but seldom attempt to kill bees which have strayed to the guard bees' hive by mistake.

A paper on chemo-reception in the honeybee was then read by Mr. G. D. Glynne Jones (Seale-Hayne Agricultural College). He pointed out that laboratory experiments with honeybees are often valueless since the bees do not behave normally; on the other hand, it is impossible to control all the variables in the field. He therefore carried out his experiments in a glass-house where many of these disadvantages could be eliminated. While attempting to measure the effectiveness of certain substances such as phenol, acetic acid and dimethylphthalate as bee-repellents, he obtained results which showed that the bees' response follows definite patterns, some of which appear to be of interest in throwing light on the mechanism of chemo-reception in the honeybee. The responses of honeybees to sucrose solutions containing concentrations of phenol ranging from 0·1 to 0·000001 per cent were measured using different techniques. In one series of experiments the bees were offered an alternative to the test solution in space; in another series an alternative was offered in time rather than space. When the alternative was offered in time, a distinct sigmoid response curve was obtained involving a very narrow range of concentrations, a solution of 0·01 per cent being completely acceptable whereas a 0·05 per cent solution was completely unacceptable. But, when the alternative was offered in space, a double response curve was obtained, the concentrations involved ranging from 0·05 to 0·000001 per cent.

Mr. Glynne Jones said that, when the alternative of unadulterated sugar syrup is offered in space, it may be assumed that concentrations of phenol above 0·000001 per cent are detected by the olfactory sense organs of at least some of the bees, and a proportion chooses the pure sugar syrup. As the concentration of repellent is increased above this level, the proportion of bees choosing pure sugar syrup also increases until a maximum is reached, after which further progressive increases in concentration result in reduction in the repellent effect. This reduction may be due to the fact that the olfactory sense organs become very quickly fatigued when exposed to these concentrations of phenol, or because these sense organs in the bee are specially adapted for appreciating very low concentrations of stimulants. This fall-off in response soon ceases if the concentration of the repellent is further increased above a certain level, and this may be due to irritation of the common chemical sense of the bee. This argument is strongly supported by the results obtained when the test solutions are alternated with pure sugar syrup in time instead of space. Under these conditions there is a direct conflict between the stimulus inherent in the bee to collect food and the power of the chemical to act as an irritant and elicit an avoidance reaction. A much narrower range of concentrations is involved which still has the same concentration of 0·05 per cent as its upper limit. Although the same pattern of behaviour was always obtained, it was found that the concentration of phenol which was capable of repelling all the bees fluctuated with different colonies at different times of year between 0·04 and 0·2 per cent. It was also reported by Mr. Glynne Jones that he has observed bees which were flying over test solutions touching the surface of the liquid with the tarsi of their hind-legs, and suggested that perhaps these bear olfactory organs. At the close of his paper he showed a short film of some of his experiments.

The discussion which followed the afternoon papers was very brief and consisted of a few questions addressed to the speakers rather than a discussion on the behaviour of social insects.

CHEMICAL ENGINEERING

THE growing appreciation of the importance of chemical engineering was evident at the recent meeting in Belfast of the British Association, when Section G (Engineering) devoted a session to the subject of education and training in chemical engineering, at which, under the chairmanship of Sir Ben Lockspeiser (president of the Section), papers were presented by Prof. D. M. Newitt (Courtauld professor of chemical engineering, Imperial College of Science and Technology, London) on "The Training of Chemical Engineers", and by Dr. E. H. T. Hoblyn (director, British Chemical Plant Manufacturers' Association, London) on "The Chemical Engineer in Industry". The discussion was opened by Sir Harold Hartley (past president of the British Association and of the Institution of Chemical Engineers). The contents of the two papers, together with points from the discussion, are summarized in this article.

The rise of chemical engineering as a primary technology is one of the direct consequences of industrial and economic developments which are still taking place. It may be said to owe its origin to the big expansion in the heavy chemical industry and to the simultaneous growth of new industries, resulting from intensive scientific research during the latter half of the nineteenth century. There was at that time a growing conviction that empirical methods of plant design, based mainly upon trial and error, could no longer meet the needs for better process control and for higher operating efficiencies and would have to give place to more scientific procedures. George E. Davis, one of the pioneers of chemical engineering, first began to lecture on the subject in 1887, and his well-known "Handbook of Chemical Engineering" was published in 1901. The introductory chapters of this book should be studied by anyone in doubt as to the true functions of a chemical engineer.

The new branch of engineering, however, made slow progress in Great Britain and, as has so often happened, it was left to Germany and the United States to build up those renowned schools of chemical technology and chemical engineering which, during the inter-war years, gave them such an outstanding lead in the international race for higher industrial productivity. In Britain we now have to face the task of recapturing some of the lost ground and, by increasing our facilities for higher technological education and vocational (technical) training, of making available to industry the skilled men required, at all levels, for the purpose.

But, in the interval, the problem has increased in scope and complexity. Technological, economic and social factors are now so closely interwoven in the structure of the modern State that higher technological education must aim at providing not only for the vocational requirements of the technical specialist but also that wider culture essential to those destined for leadership in industry and commerce. It is in this broader context that the training of chemical engineers should be considered.

There is a great deal of evidence to suggest that our industries have, over the course of years, lost the initiative in the development of new processes and products; and numerous examples might be quoted in which inventions and discoveries made by British scientific workers have been left for exploitation abroad. The growing practice of paying royalties to foreign competitors on this count is, in every respect, undesirable; not only is purchased 'know-how' always out of date, but also the practice denies to our technologists those opportunities for widening their experience and displaying their skill and initiative which are so necessary if we are to compete on level terms in the world's markets.

It was pointed out in the Dunsheath report on "Universities and Industry" (published by the Anglo-American Council of Productivity) that many Americans believe that their large numbers of chemical engineers have been an important factor in the rapid progress of industry in the United States. During 1949–50 the number of first degrees in chemical engineering in the United States was 4,529, to which must be added 712 master's and 178 doctor's degrees. It is doubtful if in Great Britain the output of chemical engineers from graduate and postgraduate courses will exceed 250 in 1953. Dr. Dunsheath's team was impressed by the importance attached to chemical engineering in the United States, and reported that this is a field to which American industry looks for a large and increasing number of its graduates. It is not too soon, therefore, that so much attention is being focused on the training of chemical engineers in Britain.

The objective of a chemical engineering training is, in the words of Prof. W. K. Lewis, "the development of the capacity of the student when faced with a new and unfamiliar situation, to handle it with a competence, involving skill, initiative and leadership". Industry must ensure that, when such men are available, opportunities are offered for the exercise of their talents.

The main types of work in which chemical engineers find employment in the chemical and allied industries, including the gas and oil industries, are research, development and design of plant; construction and installation of plant; process control and plant operation; plant maintenance. The nature of the work, the type of man employed and the level of qualification required all vary from job to job and from section to section of the industry.

Chemical plant manufacturers use chemical engineers for research and for designing and installing plant and handing it over to the customer in a satisfactory operating condition. Such work is fundamentally the same whether the plant is to be used in the chemical, gas or oil industries, and requires to be carried out by fully qualified men of high technical ability and preferably having had some plant-operating experience. The plant manufacturer also employs chemical engineers on his sales staff.

The chemical and allied industries employ chemical engineers in two very different spheres which require different levels of qualification. In the first place, the chemical industry uses them for research and development and the subsequent design and installation of plant for its own particular processes. This often involves the linking-up of specialist equipment supplied by a number of plant manufacturers. Such work may also include the costing of the plant and process and its comparison on technical and commercial grounds with an alternative process. A fully qualified chemical engineer is required for such duties, and he must be competent to work closely from the outset of the project, on one hand with the chemist who has evolved the process in the laboratory, and on the other with the civil, mechanical and electrical engineers who will be concerned with the erection and servicing of the plant and the structures which support it or the building which houses it. The chemical industry also employs chemical engineers for plant operation and process control. While large numbers are employed in this way, the number could, with advantage to productive efficiency, be greatly increased, if men with the right type of training were available in sufficient quantity; a lower level of training can normally be accepted for such work, for which chemical engineers with the Higher National Certificate (to whom reference is made later on in this article) should be admirably suited.

The oil industry and the gas industry, like the chemical industry, use chemical engineers for design and development work and for process control and technical supervision.

It is clear, then, that in the chemical and allied process industries and in the engineering industries which serve them there is tremendous scope for chemical engineers of varying levels of competence and inclination.

It has been pointed out that chemical engineering constitutes a distinctive discipline which embraces the whole of that body of applied science utilized in transferring a process from the laboratory stage to large-scale production; it is, in addition, concerned directly or indirectly with the economics of production and with the social implications of new scientific discoveries. The range of subjects to be covered is therefore extensive, and any endeavour to insist upon a high degree of proficiency in all the sciences included in the definition would be impracticable. A thorough grounding in the fundamental principles of the physical sciences is essential, but attention should thereafter be directed towards those special applications which constitute what are now generally known as the unit operations and unit processes of chemical engineering. In addition to this later study, as much of the groundwork training as possible should be carried out in the chemical engineering departments.

Any endeavour, therefore, to base a first-degree course in chemical engineering upon any synthesis of existing courses in chemistry, physics and mechanical engineering is unlikely to be successful. The only feasible compromise is that by which chemical engineering may be taken as a postgraduate subject following upon a first degree in chemistry or mechanical engineering; this method, however, involves an additional one or two years of study and carries with it no very tangible compensating advantages.

The most significant advance which has been made recently in the scope of chemical engineering training in Britain is the establishment of Higher National Certificates in the subject; the courses to this level will be taken by students holding a National Certificate in chemistry or engineering.

Industry should welcome these new courses, which will produce what have already been described as the 'non-commissioned officers' of the chemical and chemical-plant industries, which must ensure that sufficient raw material is forthcoming from their ranks to warrant the establishment of Higher National Certificate courses in various centres. Industry must also ensure that it uses these 'non-commissioned officers' properly. First, they should be employed at a level of work suited to their training —in some cases this should enable better qualified men to be released for more responsible duties, while in others it should enable more chemical engineers to be used on duties for which at present they are sadly lacking, such as plant and process control, as mentioned earlier. Secondly, industry must provide the 'non-commissioned officer' with the incentive of promotion, where competent, to 'commissioned' rank.

From the educational point of view, one of the important problems common to all categories of technology is the emphasis which should be given to works experience as an integral part of a university training. The purpose of introducing a student to industrial life during his university career is to impress upon him at an early stage that this work has to form part of a complex structure, other component parts of which are labour and management and the economics of production; but nothing can replace the first-hand experience gained by direct contact with men and things.

Two alternative methods have been adopted to this end in Great Britain, one based upon vacation work and the other upon sandwich courses: in the former, the student is expected to devote some eight weeks of at least two long vacations to employment in a works; in the latter, more extended periods of employment are sandwiched between attendance at the university. There is not much to choose between the two, and both depend for their success upon the student being able to identify himself with the routine and life of the works and being given definite duties and responsibilities. In all circumstances, he will pick up something of value from such industrial contacts and, when the courses are carefully planned, the benefit he obtains is important and far-reaching.

In general, first-degree courses in chemical engineering extend over three post-intermediate years, the first two of which are devoted to the physical sciences and to certain branches of mechanical engineering and mathematics, and the final year to unit operations and processes. It cannot be held that such a short period is sufficient to enable any comprehensive syllabus to be covered in its entirety, and it is particularly important to guard against the dangers of introducing so much detail that the student fails to obtain a broad perspective of his subject. For this reason, an extension of the course to a fourth year, with all the formal apparatus of lectures, tutorials and examinations, is not altogether desirable. The atmosphere of impending examinations is not conducive to independent thought and inquiry; and, if we wish to foster and develop initiative and enterprise, there must be a period during which the student can, under direction, begin to apply his knowledge. In some respects, this end is attained by one or two postgraduate years devoted to original work. In the case of selected students the time so spent is undoubtedly of great value. The planning of a systematic piece of research, the devising of new experimental methods and techniques, the critical appraisal and discussion of results bring out qualities in a student which no system of examinations can hope to reveal. But it must be recognized that all students are not temperamentally or intellectually fitted for research work, and no useful purpose is served by forcing them to spend one or two years in a distasteful occupation.

If we remember, however, that the technologies aim at the application of fundamental principles to practical problems and at the introduction of new methods and techniques into industrial practice, it becomes possible to devise a postgraduate course which will entail investigations of a more practical character than those generally included under the heading of fundamental research.

There is no reason why such investigations should not, in suitable circumstances, be undertaken by teams of students rather than by individuals, and in co-operation with industry rather than in the isolation of a university laboratory. This matter has been referred to indirectly in the Cremer report on chemical engineering research (published by H.M. Stationery Office for the Department of Scientific and Industrial Research), which emphasizes the importance of the functional analytical approach to chemical engineering research.

As the result of such a system of training, the graduate should enter industry with a background of fundamental science, with some knowledge of industrial organization and with a sound understanding of the basic operations of chemical engineering. He will not be familiar with the practice of any one industry nor with those technical details of plant operation which can only be acquired by works experience; and it must be recognized that some time will elapse before he can be expected to make his full contribution as a technical specialist. He should, however, be competent, at the outset, to undertake design and development work and to bring to it those qualities of initiative, originality and adaptability which are so urgently needed in industry to-day.

It is appreciated by industry, however, that it must be prepared to train the graduate further after he leaves the university, and some firms in the chemical plant field and elsewhere have developed two-year trainee courses for chemical engineering graduates.

Finally, it will be evident that chemical engineering differs essentially from those technologies which are confined to the principles and practices of particular industries or of groups of related industries, and that the strong suit of chemical engineers is that they can, by the generality of their training, be regarded as a mobile force of technologists able to move from industry to industry as economic conditions dictate.

Engineers must therefore give their support to this fourth primary technology; it is complementary to the older technologies—not competitive with them—and must have a place in their team, for on such team-work so much of the future industrial prosperity of Britain depends.

THIRTEENTH INTERNATIONAL HORTICULTURAL CONGRESS

THE thirteenth International Horticultural Congress was held in London during September 8–15. It was opened on the morning of September 8 by Sir Thomas Dugdale, the Minister of Agriculture and Fisheries. Lord Aberconway, president of the Congress, and Dr. H. V. Taylor, vice-president and chairman of the National Organizing Committee, also spoke. Lord Aberconway particularly stressed the importance for horticulturists as well as for botanists of the stability of names of the more widely grown plants, and meetings of the International Committee on Horticultural Nomenclature and Registration were held every day throughout the Congress.

This was the first International Horticultural Congress since the one in Berlin in 1938 and, as befitted the times, the main theme of the Congress was the discussion of methods by which new developments in horticulture, plant breeding and the control of pests and diseases have raised and can raise further the world production of food and other economic crops. Each morning there were general lectures which were considered as being of wide importance to horticulturists, while in the afternoon the Congress divided into seven sections dealing with fruit growing, vegetable growing, ornamental plant growing, plant breeding, environmental control, seeds and tropical and sub-tropical horticulture, respectively. As far as possible, summaries of the general lectures and full copies of the papers prepared for sectional meetings were made available in advance to Congress members

Throughout the Congress the reliance of modern horticulture on scientific research was stressed, particularly in the fields of genetics and cytology and plant physiology.

The role of climate and its influence on plant growth was discussed by Dr. F. W. Went, of the United States. In particular he described the modifications in various factors, such as temperature and humidity, which can be obtained by artificial means such as cultivation in greenhouses or against walls, and their effect on the plants cultivated, and was able to bring under a scientific scrutiny many traditional horticultural methods. Other aspects of this problem were discussed by Prof. Pierre Chouard, of France, and Dr. J. W. M. Roodenburg, of the Netherlands. Prof. G. E. Blackman, of Oxford, showed his methods for making an analysis of the effects of seasonal light intensity and temperature on the growth of plants in the vegetative phase with special reference to the English bluebell, *Scilla non-scripta* (*Endymion non-scriptus*), and the effects of shading on growth and development. He was able to show that for each plant it is possible to estimate the light intensity at which growth will be optimal. The control of photoperiodicity by practical methods and the effect of artificial lamps on growth were discussed by several speakers. Dr. J. W. M. Roodenburg showed that the low-tension neon lamp giving a red-orange light and the ordinary incandescent lamp were effective in increasing growth in periods of low light intensity such as the shorter days of winter. Radiation from the red end of the spectrum appears to be effective in promoting the flowering of many long-day plants such as sugar-beet, but retards flowering in the case of short-day plants. Prof. F. G. Gregory also gave a most interesting paper as a general background to recent physiological research in the control of growth and reproduction in plants by environmental factors.

Prof. K. Mather, of Birmingham, in a general lecture on the relation of genetics to plant breeding, gave some pointers for the production of new horticultural crop plants through polyploidy and other factors, such as the variation induced by the use of ionizing radiations like X-rays and by certain chemicals. He confessed, however, that we still have no clue as to how to produce direct mutations, or even as to whether this is possible. The importance of heterosis or hybrid-vigour was stressed by several other speakers, particularly by Dr. Gordon Haskell, and the effects were well shown by the hybrid strains of onion produced by Dr. H. A. Jones, of Beltsville, United States. In this section Dr. S. L. Emsweller, also of Beltsville, read a fascinating paper on developments in plant breeding due to the use of colchicine, a substance which, by inducing polyploidy, has opened the door to many interesting new combinations of genes. The effects of polyploidy on sterility were mentioned by several speakers, and this is obviously a subject which requires further study.

The section on fruit growing was a strong one, and Prof. T. Wallace, of Long Ashton, Bristol, gave an introductory general lecture entitled "Some Aspects of the Mineral Nutrition of Horticultural Plants". Prof. Wallace has made a special study of the effects of deficiencies of mineral trace elements in the cultivation of fruit, and this paper gave a valuable summary of a field of obvious interest and importance to the practical grower and one in which, once the correct diagnosis has been made, the cure can be effected with reasonable certainty. The work of the East Malling Research Station in Kent in standardizing root stocks for apples and pears is now well known and part of the common horticultural practice of the fruit grower, but Dr. Beryl Beakbane described some of the scientific reasons behind the effects of particular rootstocks in a paper on the anatomical structure in relation to rootstock behaviour, while Mr. A. P. Preston, also of East Malling, discussed some new apple rootstocks. The proportion of bark, that is tissues outside the cambium, to wood in the lateral roots of clonal rootstocks has been found to be related to the effect of the rootstock on the size of tree at maturity, rootstocks with a large amount of bark being the most dwarfing. Mr. Preston described a new series of apple rootstocks resistant to woolly aphid. These were bred jointly at East Malling and the John Innes Horticultural Institution, and more than twenty new rootstocks have been bred and selected out of 3,758 seedlings. Damage from spring frosts has proved one of the most difficult problems with which the grower of fruit in Britain has to contend. Dr. W. S. Rogers, also of East Malling, described the new technique of continuous water sprinkling for protection from frost, the main heating effect coming from the release of the latent heat of freezing, 80 calories per gram, as the water turns to ice. A precipitation rate of 6 mm. per hour was found to be the most effective and would protect most fruits from a temperature of 21·5° F. In this section one of the most interesting papers was given by Prof. H. B. Tukey, of the United States, in which he described the uptake of nutrients of the leaves and bark of fruit trees and the use of radioactive isotopes for following the nutrients through the tree. This treatment was shown to be effective also in winter when the tree appeared dormant.

In a combined session on plant diseases and purity of stocks, Mr. W. C. Moore stressed very strongly the importance of ensuring really healthy plant material before it is moved from country to country. The introduction of major pests with plant material is unfortunately only too well known and common an experience. Virus diseases are one of the most difficult problems that horticulturists now have to face, and in his paper on the serological diagnosis of plant diseases caused by virus, which he supported with a film, Prof. E. van Slogteren, of the Netherlands, showed how many virus diseases can at any rate be diagnosed by serological methods, a diagnosis which is independent of the symptoms of the plant.

A paper of great interest on the use of 'Krilium' as a soil conditioner, by Dr. A. J. Lloyd and Dr. C. E. Morgan, of Monsanto Chemicals, Ltd., was presented in this session, and a film was shown demonstrating the power of 'Krilium' to retain a crumbly soil structure and for the treated soil to retain drops of water without disintegrating. 'Krilium' was described by the authors as "a new synthetic polymeric electrolyte of a resin type, which by reason of its high anion potential, possesses large numbers of reactive groups in the molecule". It is understood that tests are proceeding in Great Britain, and it is to be hoped that soon this material, which is already on the market in the United States, will also be available in Britain.

In a Congress to which more than a hundred different papers were presented by speakers from twenty-seven different countries, it is obviously impossible to do more than touch on a few of the aspects of the very varied mass of material which was available. The report of the Congress will be published through the Royal Horticultural Society, Vincent Square, London, S.W.1, in due course.

In the field of the nomenclature of horticultural plants, a revised International Code was worked out during the Congress and will shortly be published as an interim code prior to submission to the next Horticultural Congress, which it is anticipated will be held in Holland in 1955 or 1956. The Congress also laid great stress on the importance of the registration of the names of cultivated varieties, and in a resolution recommended that an International Registration Authority should be set up as soon as practicable for each genus or group of genera in which cultivated varieties are numerous. The Congress also passed unanimously two resolutions on nomenclature for transmission to the next International Botanical Congress. It put on record that it was "strongly of the opinion that the interest of increased stability in the nomenclature of cultivated plants would be served by incorporation into the International Code of Botanical Nomenclature of the proposals for *Nomina Specifica Rejicienda* set out in Taxon I, No. 5 (1952) and urged their adoption at the next International Botanical Congress". It also recommended in a resolution that any provision of this nature should "allow for the rejection of certain earlier homonyms as well as earlier synonyms, and while appreciating the technical difficulties involved, urged the appropriate botanical authorities to make every effort to overcome them". Mr. J. S. L. Gilmour, director of the Cambridge Botanic Garden, was appointed chairman of the International Committee for the Nomenclature of Cultivated Plants.

Other resolutions of the Congress were passed (1) in favour of the establishment of a horticultural bureau in the Food and Agriculture Organization; (2) in support of the recommendations of the International Plant Protection Convention and for increased facilities for the exchange of experimental material between country and country; (3) in support of the encouragement of research into the fundamental problems of plant physiology; and (4) for the setting up of a small working party for considering an international method for recording light values on the lines of the Dutch Committee.

PATRICK M. SYNGE

CHEMICAL RESEARCH LABORATORY, TEDDINGTON

OPEN DAYS

FOR the sixth year in succession the Chemical Research Laboratory, Teddington, of the Department of Scientific and Industrial Research, held a series of open days to which the director invited representatives of industry, universities and government departments. This year the open days were during September 23–26, and the attendance at all sessions indicated that there is no slackening of interest in this annual event.

A special feature this year was the new radiochemical building which has been specially designed and constructed, under the supervision of the Ministry of Works, for work with radioactive materials. It incorporates many modern features which make it one of the finest of its kind in Great Britain both for work with radioactive materials and for general chemical research. This building, with its associated pump house and tank farm, occupies an area of some twelve thousand square feet sited about a hundred yards from the main Laboratory block and is constructed of red brick with stone facing to conform to other buildings in the area. It comprises administrative offices, laboratories, plant room and service void, and pump house and tank farm. The administrative offices form a single-story section near the main entrance to the building and comprise an entrance hall, offices, conference room (also used as staff room), and cloakrooms which are provided with special facilities for changing and washing.

The main part of the building consists of two large laboratories and a number of smaller rooms divided, in part, by a central passage. Immediately beyond the cloakrooms and on one side of the passage are two laboratories concerned with research on the application of ion-exchange resins to the separation of metals. In these rooms an exhibit showed the development of a method for separating gold from other metals, such as iron, copper, silver, nickel, cobalt and zinc, in cyanide solution by an anion-exchanger. In this process, gold is removed from the resin by eluting with a mixture of acetone and hydrochloric acid. The other metals are eluted with aqueous solutions of salts such as sodium cyanide and potassium thiocyanate.

On the opposite side of the passage from the foregoing laboratories is a suite of rooms dealing with the measurement of radioactivity and allied topics. These laboratories comprise a counting room completely screened from electrical interference, a main laboratory for the measurement of carbon-14 (including apparatus for low-activity measurements and a microscope for scrutinizing tracks on photographic plates), and a dark-room showing apparatus for the determination of radioactivity by measurement of scintillation in a liquid medium using solutions of *p*-terphenyl as the scintillator for radioactive material. A number of other items used in measurements of activity were shown in an adjoining laboratory.

Beyond the rooms already mentioned is a group of small laboratories and rooms. These laboratories, which can also be used as offices, are designed for one worker or for special purposes. Exhibits shown in two of these rooms included an automatic resin-life tester for determining how long an ion-exchange resin will stand up to continual re-use, and an apparatus for the continuous determination of metals by a polarographic method. Two further rooms contain balances and physical apparatus used in analytical work. Of special note is a nephelometer for turbidimetric determination. Beyond these small rooms is a large analytical laboratory containing eight double-benches, ancillary fume-chambers, dry benches for furnaces, washing-up sinks and built-in desks down each side of the laboratory. This laboratory deals with analyses of minerals and ores and with research on analytical methods. An exhibit of chromatographic methods using paper strips and columns was shown here, and particularly noteworthy was the method developed for determination of niobium and tantalum in minerals, ores and other substances. A small adjoining laboratory is devoted exclusively to fluorimetric methods, while a larger room is concerned with the separation of metals on paper strips using radioactive tracers, which are detected and determined on a special scanner built in the Radiochemical Group for this purpose.

The rest of the laboratory space is used for research work on the extraction and recovery of valuable metals from minerals and ores. A large room is available for operating with larger quantities of material than is possible in an ordinary laboratory. This large laboratory contained exhibits dealing with ion-exchange methods, precipitation under *p*H control and other techniques. Associated with this work are three smaller laboratories for research and control work, and a grinding room. The grinding room includes an ore storage annexe and contains a ball mill, hammer mill, mechanically operated screens, and an electromagnetic separator for preliminary ore treatment. This room is provided with a separate ventilation system to guard against hazard due to dust.

The plant room contains the machinery for ventilation and other items. Incoming air is filtered, washed and warmed before passing to the laboratories. Air is extracted through the fume chambers in the laboratories and passes through an electrostatic precipitator before ejection to the atmosphere through a 60-ft. chimney. This ventilation system is designed to provide at least 80 linear feet of air a minute through the fume chambers. A service void forms a second story to most of the building, and houses all the ducting and services. It provides a very colourful but orderly sight, and repairs can be carried out with minimum disturbance to the laboratories underneath.

The disposal of liquid effluent has also been carefully considered. All liquid waste from the laboratories passes through polythene piping to one of three stainless-steel delay tanks (500 gal.), where it is monitored for radioactivity. The liquid is then either left to allow time for activity to decay while the other two tanks are used, or pumped to one of two larger tanks (5,000 gal.) for dilution, or pumped directly to the drain, depending on the activity present. Provision is also made for chemical treatment in the smaller tanks and disposal by tank truck if necessary.

In the Corrosion Group of the Chemical Research Laboratory, work on the high-temperature corrosion of steel has been supplemented by a new research on oxidation by flue gases ; this is intended to assist in the development of a ferritic steel suitable for boiler superheater tubes operating at temperatures above the present normal maximum. The apparatus used consists of a tubular furnace in which the weight increase of several specimens can be measured *in situ*.

An interesting exhibit was an automatically controlled apparatus of the weatherometer type for accelerated corrosion testing. Constructed of 'Perspex', this permits continuous or intermittent exposure of specimens to spray (simulating either industrial or marine atmospheres) and infra-red and ultra-violet radiation as desired. A recently recognized ('filiform') type of corrosion which appears as worm-like tracks on plain or lacquered steel plates is being investigated ; examples produced in the laboratory were exhibited. The mechanism of corrosion inhibition by sodium benzoate and potassium chromate is being studied by radioactive tracer methods and by electrode potential decay curves. The practical application of inhibitors has been extended by the formulation of corrosion-inhibitive greases and thixotropic pastes. In electrochemical studies of paint films on immersed steel, special attention has been given to the estimation of the amount of water absorbed by the paint.

The Pure Metals Committee of the Chemistry Research Board continually collects and examines information on the availability of metals of high purity and, in addition, carries out analyses of such materials. In certain cases samples of the purest obtainable metals are kept in stock, and these can be made available to workers in other laboratories for their researches. At present twenty-three metals are kept, twenty-two of which were shown in the exhibit of the Inorganic Group. Also on view were samples of highly pure germanium and germanium dioxide in which the arsenic content had been reduced to one part in 10^8–10^9. These were purified by a process developed in the Laboratory and for which a patent application has been made. The process of purification has been studied by the use of radioactive arsenic.

Results of investigations on the production of fertilizers have been published and communicated to the industry. Further work in this field is confined to some more-specialized aspects, notably a study of the production of dicalcium phosphate. A wide range of equipment was shown in the microanalytical and spectrographic laboratories, including apparatus for the determination of active hydrogen by means of lithium aluminium hydride and a spectrum projection comparator.

One of the direct services of the Organic Group of the Laboratory to industrial and other laboratories is the supply of extremely pure organic compounds as standards for the calibration of mass spectrometers and for ultimate reference in other physical methods of analysis. Samples of thirty-six such standards were shown which are all available on request. Recent advances in chemotherapy have emphasized the potential importance of certain of the homologues of pyridine, and special attention has been given to the devising of methods for their recovery from crude-tar bases, and to the establishment of suitable analytical techniques. Jointly with the Physics Division of the National Physical Laboratory, a study of the thermochemical properties of pyridine homologues has been started.

Preparative work of the Organic Group has included the synthesis of a supply of a cinnolylguanidine derivative (at the request of the Medical Research Council) for large-scale trial as a trypanocide, applications of the Kolbe–Schmidt reaction, and new syntheses of organic compounds containing isotopic carbon. Use of naphthalene labelled with isotopic carbon has been made in a method of estimating the naphthalene content of tar oils. The method would be suitable for use in studies of the effectiveness of naphthalene extraction in large-scale processes.

In the High Polymers Group, work on semipermeable membranes and ion-exchange resins was shown. The behaviour in non-aqueous systems of membranes prepared from polyvinyl alcohol is of outstanding interest. Using membranes of this type, polymer molecular weights from one million to two thousand have been determined by osmometry; in no case was there evidence of solute diffusion through the film (*J. Chem. Soc.*, 3190; 1952). Statistical analysis of the results has shown that the relationship between osmotic pressure and concentration is best satisfied by the equation, $\pi = aC + bC^2$, where a and b are constants. Simple osmometers (capacity about 3 ml.) based on the Zimm–Meyerson design have been constructed for use with polyvinyl alcohol membranes. A novel form of reversed-phase partition chromatography was exhibited. Cross-linked polystyrene beads are allowed to swell in a carbon tetrachloride solution of the water-insoluble complexing agent, for example, dithizone. The swollen beads behave as selective absorbents and may be used for the recovery and separation of metals from aqueous acid solution.

Another service of the Chemical Research Laboratory is the supply of bacterial cultures of industrial and research interest. The National Collection of Industrial Bacteria, within the Microbiology Group, now maintains some six hundred strains, most of which are preserved in the freeze-dried state. Methods of classification and maintenance were demonstrated. Responsibility for the maintenance of 'official' cultures of antibiotic-producing organisms has recently been assigned to the National Collection by the United Nations World Health Organization.

Fundamental research on the sulphate-reducing bacteria has included a study of their oxidation of lactic, malic, pyruvic and other acids with sulphate as oxidizing agent, and the discovery of a 'sulphate-free' fermentation leading to ethanol and acetic acid. Work on their utilization of hydrogen has shown that this can result in the reduction of fumaric to succinic acid. Evidence for a co-hydrogenase, replaceable by methylene blue, has been obtained. Investigations on the microbiological production of sulphur and sulphide from sulphate are in progress at the Laboratory and at the Microbiological Research Department (Ministry of Supply) at Porton. At the latter station, a continuous method of bacterial sulphate-reduction is being used; photographs and a diagrammatic flow-sheet of the apparatus used were exhibited.

OBITUARIES

Prof. C. H. Lees, F.R.S.

PROF. C. H. LEES passed away on September 25, at the age of eighty-eight. He was a man of great charm and endeared himself to friends and students. Lees possessed great patience, and he was not to be deviated from the course he had set himself by difficulties when carrying out a piece of research.

Born in Glodwick, Oldham, in 1864, he was a student at the Owens College, Manchester, becoming Berkeley Fellow in 1888. He then studied at the University of Strassburg.

In 1891 Lees was appointed senior assistant lecturer and demonstrator in physics in Owens College and became lecturer and assistant director of the Physical Laboratories of the University of Manchester in 1900. He left Manchester in 1906 to become professor in Queen Mary College, where he remained until 1930, retiring with the title of emeritus professor of physics in the University of London.

Although Lees's first claim to fame lies in the field of thermal conductivity measurements, he was a man of wide interests. In the years between the two World Wars, he had students carrying out research on problems of acoustics, elasticity, light, electricity, as well as heat. He contributed papers on A.C. bridges and on fluid flow through pipes. The technique he used in thermal conductivity measurements now finds a place in the text-books. His *Phil. Trans.* paper on the thermal conductivity of metals to low temperatures was the subject for 1908 of the Bakerian Lecture of the Royal Society.

Lees was an excellent committee man and for more than twenty years served on the Engineering Committee of the Food Investigation Board of the Department of Scientific and Industrial Research. He also served on the Safety in Mines Board.

Education was a topic of great interest to him and for a long period he served on the Kent Education Committee and the delegacy for managing Goldsmiths' College, London. For a time he was vice-principal of Queen Mary College. He served as president of the Physical Society and vice-president of the Institute of Physics.

His hobby was handicrafts, and up to within a few days of his death he occupied his time with carpentry.

In the passing of C. H. Lees we mourn the loss of one of the 'old guard' of physics of the past generation and one of the greatest of friends.

EZER GRIFFITHS

Prof. Millais Culpin

IT is with regret that we record the death on September 14 of Prof. Millais Culpin at the age of seventy-eight. He was one of the brilliant group of psychiatrists revealed by the First World War.

He studied at the London Hospital and qualified M.R.C.S., L.R.C.P. in 1902, passing the F.R.C.S. three years later. It seemed that he was prepared for a surgical career and, indeed, he practised this for a time at Shanghai. However, when the War broke out, he joined the R.A.M.C. and became interested in war neurosis. Then he served in France during 1916 and 1917 as a surgeon, but still retained his psychiatric interest. At the end of this time he was asked by Aldren Turner to work in the Army neurological hospitals and there found ample material for research. His M.D. thesis in 1919 was devoted to his findings, and the following year he published his "Psychoneuroses in War and Peace".

Culpin was then appointed lecturer in psychiatry to the London Hospital Medical School and neurological specialist to the Ministry of Pensions. In 1923 he joined in research on neurosis organized by the Industrial Health Research Board and in 1930 was made lecturer in psychology to the London School of Hygiene and Tropical Medicine. The year after, he was appointed to the chair of medical and industrial psychology, which he occupied until he resigned in 1939.

He had a remarkably lucid mind and often was able to see things from an unusual angle. His spare dry wit occasionally illuminated his points. His writing, also, showed his clear, logical thought. He published a number of books, including "Spiritualism and the New Psychology", "The Nervous Patient", "Medicine and the Man", "Mental Abnormality Facts and Theories", and, in collaboration with Dr. May Smith, "The Nervous Temperament". His best known work was "Recent Advances in the Study of the Psychoneuroses", which summarized all the work up to its publication in 1931.

Prof. Culpin was never a spectacular figure; but he leaves behind a solid basis of research and exposition which has earned him a place among the pioneers of dynamic psychology in Great Britain.

CLIFFORD ALLEN

NEWS and VIEWS

Institution of Mining and Metallurgy: New President

PROF. J. A. S. RITSON, professor of mining in the Royal School of Mines, London, has been elected president of the Institution of Mining and Metallurgy for the session 1953–54 and will take office at the general meeting to be held on May 28, 1953. Prof. Ritson was educated at Uppingham School and in 1910 took his B.Sc. in mining at the University of Durham. He acted for a time as manager of a colliery in Northumberland and then became an inspector of mines. In 1923 he was appointed to the chair of mining in the University of Leeds, where he remained until he went to the Royal School of Mines in 1935, in which year he was awarded the O.B.E. Prof. Ritson served throughout the First World War, eventually commanding a battalion of the Royal Scots, and gained the M.C. and D.S.O. and bar. During the Second World War he was director of supplies at the Ministry of Fuel and Power until the middle of 1942. Prof. Ritson is a past president of the Institution of Mining Engineers.

Illuminating Engineering Society: New President and Awards

AT the opening sessional meeting of the Illuminating Engineering Society held on October 14 at the Society's headquarters at 32 Victoria Street, London, S.W.1, Dr. W. J. Wellwood Ferguson took office as president of the Society for the session 1952–53. Dr. Ferguson, who is senior ophthalmic surgeon at the Royal Infirmary, Sheffield, and lecturer in ophthalmology in the University of Sheffield, is one of the relatively few ophthalmologists who take an interest in lighting and is the second of his profession to become president, the first being Sir John Parsons, who held the office during 1921–23. One of Dr. Ferguson's particular interests in lighting matters is the illumination of mines and miners' nystagmus, and he has published numerous papers on these subjects He is the only ophthalmologist who takes an active part in the meetings of the International Commission on Illumination, and he serves on a number of subcommittees of the National Illumination Committee and on the Light and Vision Committee of the Medical Research Council. Recently, he visited the United States to study the work being done there in the use of cortisone in connexion with certain diseases of the eye.

The Leon Gaster Memorial Premium of the Society for 1952 has been awarded to Mr. J. S. McCulloch for his paper on "The Lighting of Shipyards"; Mr. McCulloch is with R. W. Gregory and Partners (consulting engineers) of Newcastle upon Tyne. Honorary membership of the Society has been awarded to Prof. J. T. MacGregor-Morris, professor emeritus of electrical engineering in the University of London, in recognition of his many services to the Society and in acknowledgment of his pioneering work in illuminating engineering and photometry, particularly his research on the carbon arc as a standard of light; Prof. MacGregor-Morris is one of the original members of the Society and was president in 1940.

The Biological Council

THE Biological Council, which is composed of representatives of some fifteen specialist biological societies, has recently resolved to become an advisory body to the Institute of Biology. It is expected that the closer relations between the Council and the Institute—formed on the initiative of the Biological Council—will be mutually beneficial. At a meeting of the Biological Council held on September 29, the following officers were elected. *Chairman*, Dr. W. P. K. Findlay (Forest Products Research Laboratory, Princes Risborough, Bucks); *Hon. Treasurer*, Prof. F. L. Warren (London Hospital Medical College); *Hon. Secretary*, Dr. J. L. Cloudsley-Thompson (Department of Zoology, King's College, University of London). All communications should be addressed to Dr. J. L. Cloudsley-Thompson, c/o The Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.2.

Technological Education in Manchester

AT a ceremony on October 11 at the College of Technology, Manchester, which formed part of the jubilee celebrations of the College, the associateship of the College was conferred on the Minister of Education, Miss Florence Horsbrugh, and on Lord Cherwell and Alderman Wright Robinson. Although more than one speech emphasized the dependence of the economic future of Great Britain upon technicians and technologists, Miss Horsbrugh made no reference to the Government's plans for the expansion of higher technological education. She assured her audience that the claims of the Manchester College of Technology had been very fully presented to her, and that she would do her best to meet the needs of both university and non-university work there. She could not say how quickly the Government could carry out developments which would lead to a major change in the character of the College. Lord Cherwell referred to the increasing need for well-trained technologists, but also gave no indication of the Government's plans. Mr. David Cardwell, the acting principal, referred to the way in which uncertain financial backing had led to students having to abandon advanced courses before completion and urged the necessity of an extension of grants for postgraduate research. Mr. Cardwell also referred to the high quality of the part-time students and the potentialities of such students for increasing the supply of university graduates in science and technology. The City Council, he said, is pressing forward with a building programme for the College which would cost some £1,600,000.

International Nutrition Congress

THE second International Congress of Nutrition, held under the auspices of the International Union of Nutritional Sciences, has just concluded at Basle. At a meeting of the Executive Committee of the Union, attended by representatives from sixteen nations, it was unanimously decided to accept the invitation of the Netherlands members to hold the third International Congress in Amsterdam in the summer of 1954. Prof. E. J. Bigwood (Brussels) was re-elected chairman of the Committee and Dr. Leslie J. Harris (Cambridge) honorary secretary. The following national, or organizational, representatives served on the Committee: Prof. E. J. Bigwood (Belgium), Dr. Morley Whillans (Canada), Prof. H. Dam (Denmark), Prof. A. I. Virtanen (Finland), Prof. E. Terroine (France), Prof. H. Kraut (Germany), Dr. M. Demarchi (Iraq), Dr. F. Mancini (Italy), Dr. A. Seliskar (Jugoslavia), Dr. M. van Eekelen and Prof. B. C. P. Jansen (Netherlands), Mrs. B. Q. Werenskiold (Norway), Prof. E. Abramson (Sweden), Prof. K. Bernhard and Prof. F. Verzár (Switzerland), Mr. A. L. Bacharach and Dr. L. J. Harris (United Kingdom), Dr. S. G. Greenberg (U.S.A.), Dr. W. R. Aykroyd (Food and Agriculture Organization), Dr. T. Norris (World Health Organization), Dr. D. P. Cuthbertson (Scottish Group, Nutrition Society), Miss D. F. Hollingsworth (International Dietetic Congress).

Regeneration and Re-afforestation

IN *Forestry Abstracts*, Vol. 12, No. 4 (Commonwealth Forestry Bureau, Oxford, June 1951), under "Sylviculture", F. C. Hummel describes "The Sylviculture of Mixtures in some Forests in S.W. Germany". The general policy, as contrasted with the almost universal habit in Germany during the past century and before of pure coniferous crops, is now to grow conifers and broad-leaved species in mixture. This involves what is almost a revolution in sylvicultural and management methods, and the possibilities of applying them under British conditions are described. In discussing the degree in which artificial assistance is given to this new regeneration, it is mentioned that beech and other broad-leaved species are often transplanted when 4–6 ft. high; but it is necessary to prune both the roots and crowns of such large plants and to stake them. The method is not new. In the old days, when the Forest of Dean was resown with acorns, the practice was to put in at every 20 ft. or so an oak transplant of 4–5 ft. in height. The method is employed by the French in the tropical rain-forest of the Ivory Coast in West Africa. In re-afforesting work, transplants 1½–2 m. in height are used. P. Dineur discusses the ecology of *Quercus sessiliflora* (*Q. petraea*); measurements of light under various degrees of canopy closure were undertaken for seedling regeneration, using a photometer of photoelectric cell type. Sylviculturists have for years advocated the possibility of being able to ascertain the more-or-less exact light requirements of seedlings under overhead canopy. It looks as if data on this problem may be obtainable. Lessons long since learnt in India are discussed by T. S. Serevo on "Silvicultural Observations in Cut-over Areas in Ajusan, Philippines". Logging was undertaken in an over-mature Dipterocarp forest with sparse advance growth. It is impossible to remove the main stand in such a type of forest without destroying all the undergrowth, since with the removal of the canopy the forest floor dries up. The dangers of logging in tropical forests are pointed out. The lesson was learnt in Madras in the years following the First World War, when attempts were made to introduce Canadian and American methods of logging into the evergreen forests. The result was a failure and a considerable pecuniary loss. But the lesson was learnt once and for all for India. The breaking of the overhead canopy exposes the moist soil below, never before exposed, to heat, heavy rain and wind, and it is quickly dissipated; the area is then useless for agriculture and difficult to re-afforest.

National Foundation for Scientific Research, Brussels: Annual Report for 1950–51

THE twenty-fourth annual report of the National Foundation for Scientific Research, Brussels (pp. 193; 1951), covering the year 1950–51, refers to the establishment on July 26, 1951, of the Inter-University Institute of Nuclear Sciences and to the increase of its financial resources from 20 million to 25 million francs. The Atomic Energy Commission has also since established, on April 9 this year, a Centre of Studies for the Application of Nuclear Energy, which, mainly under academic direction, will be responsible for the utilization of the products of the Belgian nuclear reactor. A list of publications of the nuclear physics centres at Brussels and Louvain during 1947–51 is included; work at the Ghent centre has included technological research on the preparation of graphite and metallic uranium and on photographic emulsions, and at the Liège centre on absorbent media for gamma-rays and neutrons, the application of photographic emulsions, nuclear chemistry and the construction of a high-tension generator of the Panthenier type. During 1951–52 the Foundation has distributed sixty subsidies, totalling 3·2 million francs and including contributions towards the cost of construction of an electronic calculating machine, an oceanographic research station at La Rochelle-Pallice, an insectarium at Mentone, an epigraphic and archæological survey of the two provinces of Nejran and Hasa in Saudi-Arabia, the construction of a heliostat for the scientific station of the Jungfraujoch, for excavations at Alba Fucens, for studies on the performance of gas turbines, and for studies of the radiation of the night sky at Arosa Observatory in co-operation with the High-Altitude Research Centre at Pasadena. Details of the distribution of radioisotopes in Belgium are included in the report, to which are appended lists of recipients of grants for 1951–52 and of papers by recipients of grants published during 1950–51.

Human Relations in Industry

THE report of the conference on human relations in industry, arranged by the Ministry of Labour and National Service during March 18–20 (see *Nature*, 169, 872; 1952), has now been published (pp. 128;

London: H.M.S.O., 1952; 3s. 6d. net). It includes the text of the Minister's opening address, Sir George Schuster's address on the work of the Panel on Human Factors in Industry; Sir Cuthbert Clegg and Mr. T. Williamson's comments on the work of the Anglo-American Council on Productivity; and reports of the discussions, together with the final text of the four group reports on, respectively, the opportunity to work, the capacity of workers, wastage of man-power and the will to work. Appended to the report are the papers on these subjects issued for discussion at the conference, and the paper summarizing the findings of the industrial productivity teams of the Anglo-American Council on Productivity relating to subjects on the agenda of the Conference; also included is Sir George Schuster's memorandum on conclusions drawn from the projects sponsored by the Schuster Panel on Human Factors in Industry.

Durban Museum and Art Gallery: Annual Report for 1950–51

The report of the Durban Museum and Art Gallery for 1950–51 is the last issued under the directorship of Mr. E. C. Chubb, who has so ably controlled the remarkable progress of this institution for forty-one years. Occasion is thus taken in the report to review this long period, which is shown to be one of continuous growth accompanied by increased popularity and educational value, limited only during the past few years by restricted accommodation. Unfortunately, although a new building embodying more adequate accommodation has been advocated during the past fourteen years, circumstances resulting from the Second World War have prevented its realization.

University College of North Staffordshire: Appointments

The following appointments in the University College of North Staffordshire have recently been made: *Senior Lecturer*, Dr. A. M. Macbeath (mathematics); *Lecturers*, Dr. Monica M. Cole (geography), Miss Ruth M. Badcock and R. L. Plack (biology), Dr. D. J. O'Connor (philosophy), Mrs. P. Elizabeth Perrott (education), Dr. A. Frohlich and B. Noble (mathematics), Dr. G. F. Smith (chemistry), and A. H. Oliffe (psychology); *Assistant Lecturers*, A. Hunter (economics), W. M. Williams (geography), Dr. S. C. Nyburg (chemistry), Miss Helga M. T. Frankland (biology), and P. H. Shelford and A. F. Trendall (geology).

University of Birmingham: Appointments

The following appointments in the University of Birmingham have recently been announced: *Lecturers*, R. D. Mackey (civil engineering), K. M. Brown and W. G. Thomas (mining); *Research Fellows*, Dr. L. A. Radicati and Dr. J. G. Valatin (mathematical physics), J. J. Pick (Lucas Research Fellow in industrial metallurgy), and B. E. L. Deckker (James Watt Research Fellow in mechanical engineering).

British Society of Rheology: Members of Committee

At the recent annual general meeting in Southampton of the British Society of Rheology, members of committee were elected as follows: *President*, A. G. Ward; *Secretary*, A. P. Feltham (British Iron and Steel Research Association, 140 Battersea Park Road, London, S.W.11); *Treasurer*, Dr. J. G. Oldroyd; *Editor*, A. A. Milne; *Northern Representative*, L. Grunberg; *Midland Representative*, A. W. Richardson; *Ordinary Members*, D. W. Jopling, Dr. J. W. S. Mardles and N. Wookey.

Announcements

The autumn provincial meeting of the Physical Society will be held in the Physical Laboratories of the University of Manchester during December 18–19. The meeting will be on "Ionization Loss by Relativistic Particles" and will include speakers from the Atomic Energy Research Establishment, Harwell, and from the Universities of Bristol, Brussels, Glasgow, Leeds and Manchester. Non-members are welcome to attend. Details of the programme and application forms can be obtained from the Offices of the Society at 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

To mark the opening earlier in the year of the Textile Institute's new headquarters at 10 Blackfriars Street, Manchester 3, a series of inaugural lectures is to be given there, the speakers and their subjects being as follows: October 24, Sir Ben Lockspeiser (secretary of the Department of Scientific and Industrial Research), on "Science in Industry"; November 21, Sir Wallace Akers (a director of Imperial Chemical Industries, Ltd.), on "The Chemical Industry and Textiles"; and January 30, Mr. A. H. Wilson (research director of Courtaulds, Ltd.), on "Whither Man-Made Fibres?". Each lecture will commence at 3 p.m. Admission is by ticket, applications for which should be made to the Registrar of the Institute at the above address.

The twelfth series of postgraduate lectures organized by the Oil and Colour Chemists' Association will be given by Prof. C. E. H. Bawn, professor of inorganic and physical chemistry in the University of Liverpool, who will speak on "Autoxidative Reactions: their Chemistry, Mechanisms and Catalysis by Metal Salts". The lectures will be given at 6.30 p.m. on November 17, 24 and December 12 in the Lecture Theatre of the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1. The fee for attendance is 15s. for members of the Association and £1 for others (inclusive of a copy of the lectures). Further information can be obtained from the Association at Memorial Hall, Farringdon Street, London, E.C.4.

The Medical Research Council invites applications for the Kathleen Schlesinger Fellowship, tenable initially for one year at the National Hospital for Diseases of the Nervous System, Queen Square, London, and worth £700–1,000 a year. This Fellowship is provided from a fund established by the late Mr. and Mrs. E. M. Schlesinger in memory of their daughter; it is for the investigation of the origin and nature of cysts of the brain, and preference will be given to candidates who elect to work on the mechanisms underlying degenerative processes affecting the brain. Applications must reach the Secretary of the Medical Research Council, 38 Old Queen Street, London, S.W.1, not later than November 15.

The University of Chicago, with the financial support of the Rockefeller Foundation, is offering three postdoctoral fellowships in statistics for 1953–54. These fellowships, which are worth 4,000 dollars each, are open to holders of a doctorate or its equivalent in research accomplishment, and their purpose is to enable research workers in the biological, physical and social sciences to acquire training for the application of statistical methods to their normal work. Details of application (to be completed by February 3, 1953) and further information can be obtained from the Committee on Statistics, University of Chicago, Chicago 37.

HUMAN BIOCHEMICAL GENETICS

A JOINT SESSION arranged by Sections D (Zoology), I (Physiology), J (Psychology) and K (Botany) of the British Association was held during the recent Belfast meeting to discuss "Human Biochemical Genetics".

In his introductory remarks, Prof. L. S. Penrose (Galton Laboratory, University College, London) pointed out that the foundations of the exact study of human genetics were laid down almost simultaneously by Landsteiner in his work on the *ABO* blood groups and by Garrod in his work on alkaptonuria. These investigations, carried out between 1900 and 1902, described human characters which were found to follow simple rules of inheritance, and the tests for their presence or absence were precise. The branch of the subject initiated by Landsteiner utilized serological techniques depending ultimately, but not yet demonstrably, upon inborn biochemical peculiarities. The other branch of biochemical studies in human genetics is derived from Garrod's work, and it deals with characters identified by ordinary chemical tests or their equivalents, like colour reactions.

It is convenient to classify the known types of inborn biochemical specifications by the substances involved in the test reactions. Anomalies of protein metabolism include alkaptonuria, the amino-acidurias, such as phenylketonuria, tyrosinosis, cystinuria and beta-amino*iso*butyricaciduria (the 'T-pattern' described by Crumpler, Dent, Harris and Westall), the melanin peculiarities exemplified by albinism and the globulin specificities found in the blood in sickle-cell trait and thalassæmia. Abnormal lipoid metabolism is represented by such diseases as xanthomatosis and cerebromacular degeneration; at present this group has proved intractable for experimental investigation. Anomalies associated with carbohydrate metabolism include pentosuria, fructosuria and renal glycosuria; diabetes mellitus is only included in a very indirect manner. There is also a large miscellaneous group of conditions, not easy to classify, some associated with disease and others quite harmless; for example, gout, porphyria, congenital methæmoglobinæmia, red hair and taste deficiency.

A primary aim in human genetics is to reduce all characters so far as possible to chemical differences. In this way, the study of human constitution will gradually become an exact science freed from ambiguities and superstitions which surround the cult of physical types. Moreover, with harmful traits, knowledge of the causal mechanisms can help in planning their alleviation or cure.

Three aspects of the subject were emphasized by Dr. H. Harris (University College, London): the precise characterization of human variations in biochemical terms, the genetical analysis of traits so defined, and the study of the processes by which individual genes produce their particular effects. These points were illustrated by reference to amino-acidurias in general and especially to cystinuria, a condition first recognized by Wollaston in 1810 on the discovery of a renal stone of unusual composition. Since the introduction of paper chromatography, it has been possible to separate a classical type of cystinuria, in which cystine excretion is accompanied by excessive excretion of lysine and arginine, from other types, in which it occurs as part of a generalized amino-aciduria (for example, Fanconi syndrome, Wilson's disease). Quantitative studies using the technique of polarography were carried out in families containing cases of classical cystinuria. Those with stone formation were found to excrete on the average about 750 mgm. of cystine daily, whereas normal people averaged about 60 mgm. In one group of families studied, cystinuria segregates sharply and behaves as a single Mendelian recessive trait. In the remainder of families, three distinct types of individuals were found: the data here were consistent with the hypothesis that heterozygotes (carriers of the gene causing cystinuria in homozygotes) excreted about 150 mgm. daily and were thus distinguishable from normal homozygotes. The frequency of carriers of this incompletely recessive gene is about 3 per 1,000 in the general population.

Garrod's view on the causation of biochemical anomalies was that there was congenital absence of an enzyme concerned in performing a particular step in metabolism. This theory is easy to apply to alkaptonuria and phenylketonuria; but in renal glycosuria or cystinuria the process is not so clearly demonstrable. A block in intermediate metabolism would tend (as it does in phenylketonuria) to cause an increase of unusable metabolites in the blood-stream or tissue-fluids. This does not occur in classical cystinuria, and it is thought that there is failure of reabsorption in the kidney tubules due to a defect in one of the chemical reactions concerned in this complex process.

A detailed account of the effects of the recessive gene for phenylketonuria in its homozygous form was given by Dr. V. Cowie (Maudsley Hospital, London). In this disease, first described by Folling in 1934, about 1 gm. of phenylpyruvic acid is excreted daily in the urine. Dr. Cowie pointed out that mental impairment, usually of a severe degree, is always present, and there are many associated physical features including dilution of hair colour and postural peculiarities. The fundamental defect is a reduced capacity to metabolize phenylalanine through the normal channel by way of tyrosine. Experiments have shown that although this pathway is not completely blocked, phenylalanine accumulates in the blood and cerebrospinal fluid and is eventually excreted after deamination as phenylpyruvic acid. The way in which the mental and physical abnormalities are produced by the biochemical defect, she said, is not yet clear. However, the condition is present at birth, and attempts at alleviation by dietetic methods have so far been unsuccessful, though the possibilities of very early treatment have not been fully explored.

Besides demonstrating hereditary biochemical specificities within the human species, Garrod directed attention to the biochemical differences between species. An account of a comparative survey of urinary amino-acid patterns in a number of different animal species was given by Dr. S. P. Datta (University College, London). Most of the animals tested were in the London Zoo. Sufficient urine was placed on two-dimensional chromatograms to give up to six main spots. Glycine was almost always present, and alanine and glutamine or glutamic acid occurred very frequently. In the mouse and the binturong, however, only taurine was found. One substance of special interest, a sulphur-containing amino-acid, purified from cats' urine by Westall, was named 'cat-spot'. In most of the Felidæ it appears to be an alternative to taurine for the excretion of organic sulphur. The Kenya blotched genet has a peculiarity unique among the animals studied in that it excretes very large quantities of cystine. The question as to how so much cystine can be kept in solution in these urines might have some relevance to the study of the prevention of cystine-stone formation in man.

Dr. Datta showed that methyl histidine, which occurs variably in human urine, is always present in laboratory cats which are fed mainly on meat. It is not excreted by animals such as rats, mice, rabbits and guinea pigs, the diets of which are mostly of vegetable origin. By experiments on man, it has been possible to demonstrate that methyl histidine in the urine is probably derived from ingested anserine, a known constituent of muscle. Anserine is hydrolysed in the body to produce beta-alanine, which is further metabolized, and methyl histidine, which is excreted. Thus a peculiarity which superficially resembles an inborn trait turns out on chemical analysis to be mainly a question of diet.

Prof. D. C. Harrison (Queen's University, Belfast) dealt with the rare hereditary disease familial methæmoglobinæmia. He reviewed work done in collaboration with Prof. H. Barcroft, Dr. Q. H. Gibson and others. In methæmoglobinæmia, an abnormally large proportion of the blood pigment hæmoglobin (Hb) is changed to the corresponding ferric compound methæmoglobin ($Met\text{-}Hb$), which is useless for oxygen transport. In normal blood, the equilibrium $Hb \rightleftharpoons Met\text{-}Hb$ lies far to the left owing to the action of enzyme oxidation-reduction systems in the red blood corpuscles. These systems reduce the methæmoglobin which is constantly being formed from hæmoglobin and prevent the methæmoglobin from accumulating in more than traces. In the type of methæmoglobinæmia caused by certain drugs or (in infants) by nitrates in drinking water, the oxidation of hæmoglobin to methæmoglobin becomes so fast that the restoring enzyme systems are temporarily unable to maintain the normal level of hæmoglobin; but conditions return to normal when the offending agent is removed. In familial methæmoglobinæmia, on the other hand, the rate of production of methæmoglobin is normal but its rate of reduction is abnormally slow, so that it may accumulate to form as much as 40 per cent or more of the total blood pigment. Denny observed that large doses of ascorbic acid (acting as a reducing agent) shift the equilibrium back towards normal.

The work of Gibson has shown that the disease is due to an enzyme defect in the red blood cells; there is a shortage of diaphorase I (a flavoprotein enzyme). This shortage was demonstrated by direct assay in the blood of all seven patients who were tested. The values were in every case lower than those of any of the sixteen normal bloods used for comparison. Addition of excess diaphorase I restored full activity. The oxygen dissociation curve of the blood of the patients was found to be shifted to the left, that is, the blood parted with its oxygen less readily than normal. This, coupled with the large amount of pigment present in the abnormal, non-functional state, makes it surprising that the patients as a whole were able to lead active, energetic lives. The compensating polycythæmia which was present in the more severe cases may help to explain this.

The disease is apparently due to a mutation of the gene responsible for synthesis of the flavoprotein diaphorase I. In all three families studied, the disease appeared to be inherited as a recessive Mendelian trait. Prof. Harrison stated that quantitative studies on the blood of relatives of the patients had given no evidence for the presence of detectable genetic carriers. Treatment of the patients (which was successful in all cases) consisted of large daily doses of ascorbic acid continued indefinitely, preferably supplemented by a single dose of methylene blue after the first few days.

GROWING-POINTS IN CYTOLOGY

On the opening day of the recent British Association meeting in Belfast, a session was devoted by Section D (Zoology) to the discussion of some recent advances in cytology. The first paper, by Mr. I. C. Smith (Dundee), on the curious cytology of Pharaoh's ant, *Monomorium pharaonis* L., followed naturally on Prof. Peacock's presidential address (see *Nature*, September 6, p. 395), which earlier in the day had been concerned with some aspects of hymenopteran reproduction. Pharaoh's ant shares with many other hymenopterans the peculiarity that the males arise from unfertilized eggs by haploid parthenogenesis, or arrhenotoky, with the result that the male germ cells and much of the soma remain haploid. The females, on the other hand, develop from fertilized eggs, so that the female germ cells and much of the soma are diploid. Clearly, the eggs of virgin females can develop only into males.

Since the male germ-line is already haploid, it is obvious that no further reduction can take place in the chromosome number during the maturation of spermatozoa. In the hornet, Meves showed as early as 1904 that, during spermatogenesis, the first meiotic division, which is normally a reduction division, is abortive, while oogenesis is normal. Considerable attention has therefore been paid to the details of the first meiotic division in the spermatogenesis of Pharaoh's ant. Mr. Smith described the untidy nature of this division and the curious fact that about this time a small fragment of cytoplasm separates as a bud. Some have considered this bud to represent a vestigial cell, the remnant of a typical meiotic division; but there are now good reasons for abandoning this view. The division is, in fact, a normal mitosis, and the two daughter cells develop without any further division into spermatids and spermatozoa, which are, of course, haploid. There is therefore no stage in spermatogenesis which corresponds to a normal first meiotic division.

The meeting then passed on to consider an interesting paper by Dr. R. J. Goldacre (Chester Beatty Institute, London) on the tail region of *Amœba*. Dr. Goldacre began by tilting at the insistence of so many zoologists that the *Amœba* is an animal without form, a point of view that is perpetuated by such names as *Amœba chaos* and *Chaos chaos*. A text-book *Amœba* is said to throw out pseudopodia at random from any part of its surface, whereas the real *Amœba* has an obvious antero-posterior polarity with a well-marked permanent tail, or rear contracting end. This rear end can easily be distinguished as a group of wrinkles caused by a contraction of the cortical gel, which in the tail is liquefying to be squeezed forward up the central channel of the *Amœba*.

That the tail region of an *Amœba* is relatively permanent is shown by the fact that the animal has never been seen to reverse, even when watched for as long as a week. This fact can also be demonstrated by staining a living *Amœba* with neutral red. The stain becomes concentrated in the tail, which can then be seen to keep its identity for long periods of time. Dr. Goldacre also described how the fate of the tail region can be followed during cell division, and how the tail seems to determine the plane of the division furrow. This furrow is first evident anteriorly, and the tail region is the last part to divide and separate. He therefore suggested that the tail of an *Amœba* may play some important part in the organization of the cell, surviving possibly throughout its whole life by passing from parent to daughter.

The third contribution to the symposium was a paper by Prof. H. G. Callan (St. Andrews); but since he was unable to be present it was read in his absence by Dr. Ann R. Sanderson. A description was given of recent research on amphibian oocyte nuclei, with particular reference to their chromosomes. These nuclei have the attraction that when they have been extracted from the yolky cytoplasm they are large enough to be visible to the naked eye. Investigations have shown that there are at least two, and probably three, materials forming the nuclear sap: a fluid phase extending through a jelly phase, and probably an even more rigid centrally placed jelly in which the chromosomes are embedded. The whole is surrounded by a membrane pierced by close-packed hexagonal pores.

The chromosomes themselves have been the subject of considerable observation, the necessary preliminary being the development of a technique for their extraction. In *Triturus* newts the growing oocytes contain chromosomes in the diplotene of meiosis. These chromosomes are almost 800 μ long and are arranged in pairs joined at one or more points of contact. They are of the type known as 'lampbrush', and it is their peculiarity that loops of material sprout out from the chromosome axis and return to their points of origin. There are many structures along the lengths of lampbrush chromosomes which enable one to map them. In a given position there may be a loop which is short and thin, or long and fuzzy, and there are also well-defined regions concerned with the production of nucleoli. When fully formed, these nucleoli detach themselves and migrate to the nuclear membrane. With all these structures available for matching chromosomes, it is possible to show that the contact points between pairs of chromosomes occur in homologous regions, although they differ in different nuclei. Indeed, they show the same type of variation in position as is shown by chiasmata. The paper ended with the suggestion that the great value of this oocyte material may prove to lie in what it can teach of gene activity, for in examining these lampbrush chromosomes one may really be seeing genes in action.

The session ended with a paper by Prof. W. S. Bullough (Birkbeck College, London) on hormones and cell replacement in the epidermis. The research involved was not strictly cytological, but was rather an example of what can be achieved in biological and biochemical work by the use of cytological methods. It had earlier been shown that the most critical single factor determining the rate of epidermal cell replacement is the rate of energy-production inside the cells. Since it is known that a number of hormones affect the rate of production of energy, a study has now been made of their effect on cell division. Epidermal cells are normally half-starved for glucose, apparently because of their poor powers of absorption of this sugar from the surrounding medium. Insulin is well known to assist the uptake of glucose from the blood by stimulating the hexokinase reaction, and it was found that it also has this effect on epidermis *in vitro* as evidenced by an induced doubling of the rate of mitosis. It is also known that the pituitary growth-hormone inhibits the hexokinase reaction, and experiments have shown that *in vitro* it powerfully inhibits cell-division. This result suggests that a re-examination of the actions of this hormone is now due, and that the substance may prove to have been misnamed. Possibly its ability to promote growth may be through the induced secretion of other hormones such as insulin.

Attention was then turned to the action of the œstrogenic hormones, which also stimulate epidermal cell-division both *in vivo* and *in vitro*, and evidence was briefly reviewed which indicates that they too act by facilitating the hexokinase reaction. However, *in vivo* the stimulus they exert is only short-lived, and a reaction quickly sets in. This appears to be due, at least in part, to some stimulus to the adrenal cortex, which then actively secretes hormones similar to cortisone. Both *in vivo* and *in vitro* cortisone depresses the rate of production of energy and of epidermal mitosis. Androgens do not induce over-activity of the adrenal cortex with growth inhibition, and this fact suggests a reason for the larger body-size of so many male mammals.

The session ended with a lively discussion, ranging in subject from protozoans to cancer.

APPLICATION OF RADIOACTIVITY TO MINERAL DRESSING

THE third Sir Julius Wernher Memorial Lecture of the Institution of Mining and Metallurgy was given on September 22 at the Royal Institution before a gathering of mineral-dressing engineers who had come to London from many parts of the world to attend the first symposium on this subject to be held in Great Britain. The lecturer, Prof. A. M. Gaudin, Richards professor of mineral engineering in the Massachusetts Institute of Technology, chose for his subject "The Application of Radioactivity to Mineral Dressing".

Radioactivity can be used in three ways—as a research tool, for the control of plant processes, and in the direct separation of radioactive from inert minerals. Beta- and gamma-radiation is employed, the limitations of the alpha-rays making them unsuitable. Such properties as self-diffusion, adsorption across the liquid/solid interphase of minerals suspended in fluids, rates and site packings, as well as the mode of movement are of critical research importance in the exploration of surface phenomena used in the process of froth flotation. Prof. Gaudin's lecture not only showed some of the work which is being done but also gave fascinating glimpses of possible new methods of mineral-dressing research. In the complex field of attrition, the use of labelled particles of a closely defined size-range as part of the total mixture of wide-ranging sizes fed into an attrition mill is throwing light on the selective grinding which goes on among these sizes under controlled conditions. Natural radioactivity is in use in north-west Canada to actuate sorting mechanisms which segregate the uranium-bearing ore from inert material, and the same process is being studied for possible use with artificially induced, short-lived radioactivity (gamma-radiation) for a selected mineral such as one containing beryllium.

Another incipient aid to fundamental work promises to be the differentiation between slightly varying crystals of what are loosely grouped as the same mineral. For example, galena (lead sulphide) could be thought of as being just galena ; but minute traces of impurity and minute variations in its lattice structure and discontinuity make profound differences in its behaviour, both in study and in its practical concentration from its ores. These differences can be greatly magnified by the use of suitable radioactivating techniques.

The Lecture provided an admirable introduction to the symposium held at the Imperial College of Science and Technology, London, by the Institution of Mining and Metallurgy during the following three days, when about forty papers were presented and at which a wide variety of research and practical aspects of this important and growing technology was examined. In recognition of his distinguished services, honorary membership of the Institution of Mining and Metallurgy was conferred on Prof. Gaudin before he gave the Lecture.

RESEARCH COUNCIL OF ALBERTA

REPORT FOR 1951

THE thirty-second annual report of the Research Council of Alberta*, describing the work of the Council in 1951, again stresses the work on the bituminous oil sands ; and preparation for the Athabasca Oil Sands Conference, which was sponsored by the board of trustees of the Oil Sands Project, made heavy demands on the Research Council's staff. The terms 'bituminous sand' and 'tar sand' have now been dropped, because of their false implication, in favour of 'oil sands'. Laboratory investigations have confirmed the presence of vanadium in the oil sand, both as a mineral and as a component of the oil, especially in the resin and asphaltene fractions. Some work was done on the characteristics of the flow of sand suspensions, including a study of the friction factor in pipes, as well as on the electrical resistance of oil sand and its breakdown under a high potential difference.

A balanced programme of studies on coal included a study of the absorption spectra of oxidation degradation products of Alberta sub-bituminous coals in aqueous solution, of the cleaning of coal with cyclone washer equipment, analytical and physical testing, and of the physical properties of magnetite, Burmis iron ore, loess, limestone and tailings from a zinc refinery with reference to their suitability for the preparation of the media used in dense-media processes of cleaning coal.

A reconnaissance pleistocene survey was made of the Lake St. Ann map area, and the Gasoline and Oil Testing Laboratory again surveyed gasolines sold in the area and initiated a study of viscosity data at low temperatures on aviation lubricating oils diluted with aviation fuel, and one on the effect of storage time on preformed gum, and on 5-hr. and 16-hr. potential gum tests on aviation fuel. The pyrolysis of natural gas, the partial oxidation of butane, and the National Research Council's Pidgeon process for carbon black received attention, while irrigation soil-survey work on the Bow River project was started and the William Pearce project was continued. A re-survey of the Edmonton map sheet was commenced, and work on the Sturgeon Lake sheet resumed. The investigation of biological cycles continued, particularly with reference to the fluctuations of wild life in northern latitudes, and measurement of ultra-violet solar radiation continued with the thorium photo-cell and with a zirconium photo-cell in spite of adverse conditions. A list of publications of the Council is appended.

A WAVE-RECORDER FOR USE IN SHIPS

By M. J. TUCKER
National Institute of Oceanography

ALTHOUGH sea-waves have been recorded for a number of years using shore-connected pressure-measuring instruments or inverted echo-sounders laid on the sea-bed, collection of exact information about waves, studies of the growth of waves relative to the wind, and studies of ship motion and of coastal changes relative to the waves have always been retarded by the absence of a reliable method of continuously recording waves from a ship in deep water.

Some measurements have been made by a method in which an observer stations himself at such a height that the top of a wave comes just level with the horizon when the ship is on a fairly even keel in the trough. Much more accurate measurements have been made by stereo-photogrammetric methods using cameras with a long base-length mounted high on the ship.

Neither of these methods is satisfactory for obtaining a continuous picture of changing wave conditions, and for this purpose the best method until recently has been that employed before the Second World War by the Deutsche Versuchanstalt fur Luftfahrt for the study of seaplane landings in a variety of wave conditions. In this method a pressure recorder was suspended on a steel wire 100–200 ft. below a flat lens-shaped float : because of the rapid attenuation of wave-pressure with depth, the recorded pressure fluctuations were mainly due to the recorder following the vertical movements of the float on the surface. A correction could be made for the residual wave motion at the depth of the recorder when the presence of long waves made this necessary. The pressure fluctuations were recorded by a diaphragm connected to a diamond which scratched a spiral record on a polished steel cylinder rotated and moved along its axis by clockwork. The scratch recorder has been replaced in Great Britain by an electrical pressure recorder the output of which is transmitted to the attendant ship by wireless or by a buoyant cable, but the basic idea is the same. Measurements have also been made by an apparatus attributed to Froude and which consists of a buoyant graduated pole held vertical by a weight on its lower end and kept steady in the water by a drogue of relatively large area suspended on 200 ft. of wire from the bottom of the pole. The movements of the water up and down the pole are usually observed visually or photographed, but on a recent voyage of the R.R.S.

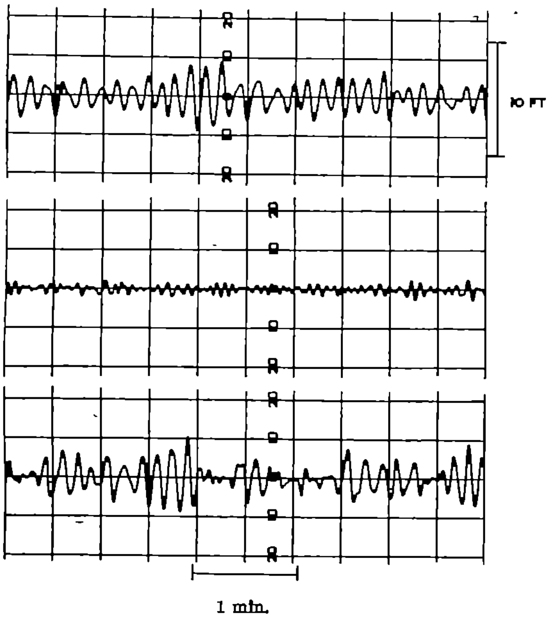

Fig. 1

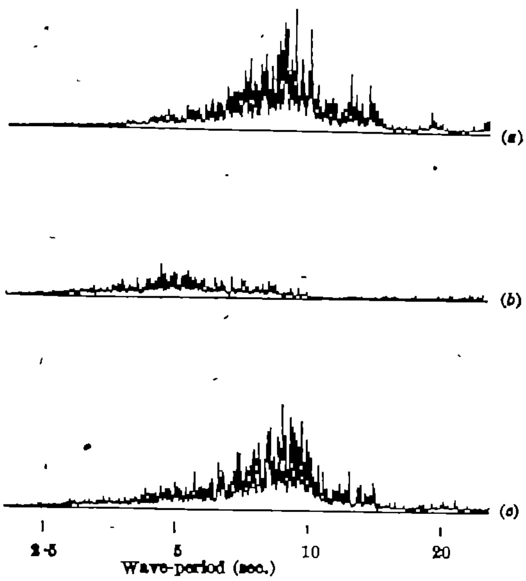

Fig. 2

Portions of records taken with the wave-recorder (Fig. 1) and the corresponding frequency spectra (Fig. 2): (a) accelerometers only connected; (b) pressure measurements only; (c) combined output giving true wave record. The records were taken in sequence, so that the wave record is not the sum of the other two records in detail. It can be seen, however, that the spectrum of the wave record is the approximate sum of the other two

Discovery II satisfactory measurements were obtained by attaching a limp air-filled rubber bag to a point below the mean water-level on the pole and communicating the changes in pressure to the ship through hose-pipe.

All these methods involve laying out apparatus from the ship and recovering it, and, if the apparatus is connected to the ship by a cable or hose-pipe, it is also necessary to hold the ship stationary to prevent the apparatus being towed through the water. These operations can be difficult, particularly in bad weather, when the results may be of greatest interest, and suitable stowage of the comparatively delicate and bulky equipment may not be easy. The advantages of a recorder contained entirely inboard are apparent.

The officers of the German research vessel *Gazelle* (1874–76) used a very sensitive aneroid barometer to measure the fluctuations in air pressure caused by the waves and the movements of the ship, but the uncertainties of this method are too great to enable it to be relied upon.

The new instrument developed by the National Institute of Oceanography is contained completely within the hull of the ship and is well suited for routine measurements. In principle it measures the height of the water surface above some point on the ship's hull and the height of this point above an imaginary reference plane. The sum of the two measurements gives the height of the water surface above the reference plane, and hence is independent of the movement of the ship. The height of the water surface above the point on the ship's hull is measured by the pressure transmitted through a small hole in the ship's side, and the displacement of the point is measured by means of a vertical accelerometer the output of which is integrated twice electronically with respect to time. To allow for the effects of reflexion of short waves from the sides of the ship, a pressure-recorder – accelerometer unit is fitted in each side of the ship, and the mean of their outputs is taken. The response of this arrangement to waves which are only partially reflected has not been rigorously calculated; but it is apparent from physical reasoning that large errors will not be introduced.

The units have to be mounted some distance below the water-line because the point of pressure-measurement must always remain below the water surface, and they will therefore not measure very short waves. If the units are 10 ft. below the water-line, the response will drop to approximately half for waves of 4 seconds period.

To measure true vertical accelerations the accelerometers should be mounted on gyroscopes or long-period compound pendulums; but, to simplify design and to reduce both the space and maintenance required, they are in practice mounted on short-period pendulums which set themselves into the apparent vertical. This results in an apparent increase in gravity (that is, an increase in the mean output of the accelerometers) when the ship moves into a wave train, because the water particle motion, and hence the ship motion in the longer waves, is in circular orbits. If this increase were truly integrated the output would drift off scale; but, by a correct choice of the time constants of the integrating circuits and by including a resistance-capacitance coupling in the circuit, the effect can be minimized and does not appear to be serious in the present instrument.

To avoid trouble from instrumental drift, the accelerometers must be very linear and give large voltage outputs. The accelerometers in this instrument have a sensitivity of approximately 30 volts/g and are linear within about 1 per cent over the range $-0\cdot4$ to $+0\cdot4\,g$.

The first of these wave-recorders, fitted in the R.R.S. *Discovery II*, the research ship of the National Institute of Oceanography, has been tested during a recent cruise in the North Atlantic Ocean. During this cruise, which lasted 2½ weeks, a gale of force 9 was encountered and waves with a maximum height of approximately 30 ft. were measured. The instrument behaved satisfactorily during this period and developed no faults. Records from the instrument were compared with those obtained from pressure and echo-sounding wave-recorders in shallow water, and with records from the electric and pole and drogue recorders as already outlined. Preliminary analyses of these results show satisfactory agreement. The overall accuracy of the instrument in its present form is estimated at ± 10 per cent.

Portions of three records are shown in Fig. 1 with the corresponding analyses in Fig. 2. (*a*) is the output of the instrument with only the accelerometers connected, (*b*) the output with only the pressure units connected, and (*c*) the combined output. The records are not simultaneous, but were taken in sequence. They demonstrate that the pressure units measure the short waves to which the ship does not respond, whereas the accelerometers measure the waves which are long enough to cause the ship to heave.

In conclusion, I would like to acknowledge the help of Mr. F. E. Pierce, who was mainly responsible for the mechanical design of the instrument.

NEW AMINO-ACIDS IN YOUNG APPLE FRUITS

By Dr. A. C. HULME and W. ARTHINGTON

Ditton Laboratory (Department of Scientific and Industrial Research), East Malling, Kent

A PRELIMINARY examination of the amino-acids present in young (10 gm.) fruits of Bramley's Seedling apples by means of filter-paper chromatography[1] suggested the presence of at least one 'unknown' amino-acid. A more extended examination of young (15 gm.) Worcester Pearmain apples indicated the presence, on two-dimensional chromatograms, of at least four spots reacting to ninhydrin in positions not attributable to any recorded amino-acid[2]. The position of these four substances (*A*, *B*, *C* and *D*) will be seen from Fig. 1, which represents a two-dimensional chromatogram of the amino-acid fraction absorbed from extracts of these young apples on 'Zeokarb 215' and displaced by 0 15 *N* ammonia, and from which a considerable portion of the asparagine (which comprises about 80 per cent of the total soluble nitrogen of the fruit) had been removed by crystallization.

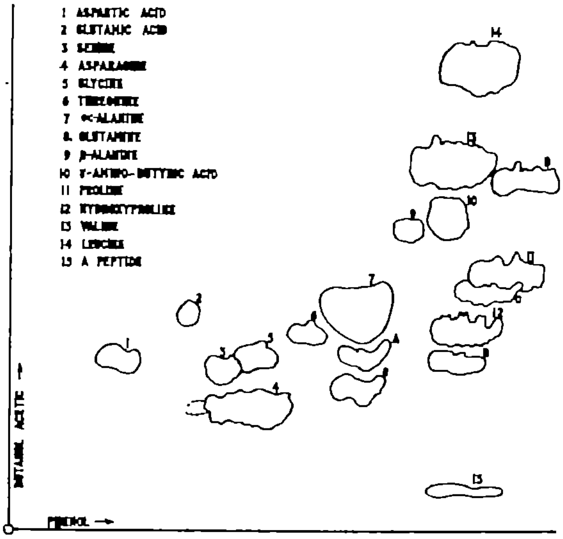

Fig. 1. Chromatogram prepared from an extract of young Worcester Pearmain apples

In more recent work substance *A* has not appeared, and substance *C* has been found to be a peptide. To isolate, for identification, substances *B* and *D*, which were clearly present in the fruits in very small quantities, extracts were made of 70 kgm. of pulp tissue from Worcester Pearmain apples (15 gm.) and the extracts suitably treated for the separation of the amino-acid fraction. By fractionation of the mixed amino-acids on a range of ion-exchange resins, a simple mixture was finally obtained which comprised practically all substance *D*, some γ-amino butyric acid, β-alanine, and a little proline and substance *B*. At this stage a peculiarity of substance *D* became very obvious. In early two-dimensional chromatograms the spot attributed to *D* sometimes gave a yellow colour with ninhydrin, sometimes a purple colour and sometimes a mixture of the two. When the purple colour was present, the ninhydrin-treated spot fluoresced a bright magenta colour in ultra-violet light. Since the two colours were never separated on conventional two-dimensional chromatograms and on single-dimensional chromatograms in butanol – acetic acid – water, it was at first thought that the 'two-colour' appearance was either analogous to the 'two-colour' spot often given by a compound such as methyl histidine or due to a peculiar structure of the compound. On careful fractionation of the simple mixture already mentioned on a lightly cross-linked polystyrene resin[3], fractions were obtained which on chromatograms gave a sequence of spots as shown in Fig. 2. Early fractions, associated with proline, gave a yellow colour with ninhydrin, middle fractions a mixed colour spot, and later fractions a purple spot (and no other ninhydrin-reacting substance) which fluoresced a bright magenta colour in ultra-violet light. In the final fractions γ-amino butyric acid, β-alanine, etc., also appeared. Thus it became virtually certain that 'substance' *D* was in fact two substances: *D*1, the acid reacting yellow with ninhydrin, and *D*2, the acid giving a purple colour with ninhydrin and fluorescing a magenta colour in ultra-violet light. By a further fractionation on a small column of the sulphonated polystyrene resin, a few milligrams each of two sets of crystals

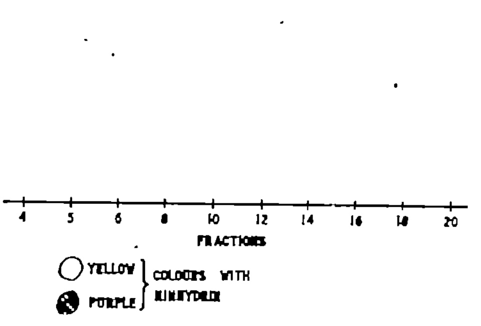

Fig. 2. Chromatogram of fractions containing amino-acids *D*1 and *D*2

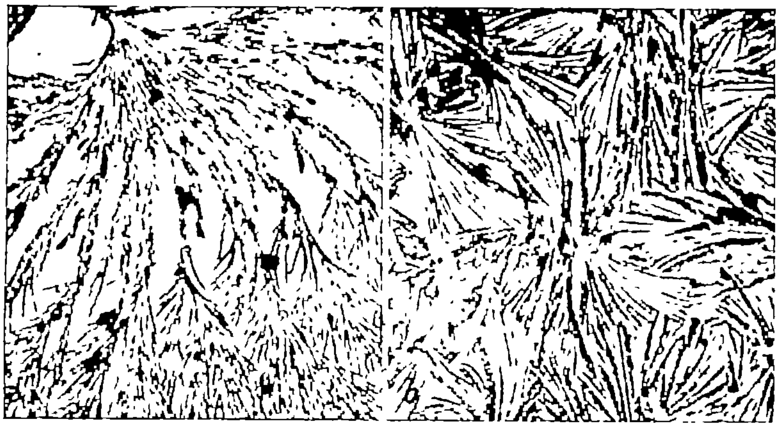

Fig. 3. Photomicrographs of amino-acids (× 35) (*a*) preparation *D*1 and proline ; (*b*) preparation *D*2

were obtained, one of which proved, on chromatographic examination, to be *D*1 contaminated with a little proline and the other pure *D*2 (about 60 mgm.). The known properties of these acids are as follow.

*Properties of D*1. (1) The acid gives a lemon-yellow colour with ninhydrin. (2) On filter paper it gives a pure blue colour on spraying with 0·1 per cent isatin in ethanol – butanol (1 : 1 v/v) and heating the paper to 110° C. for 1–2 minutes. This isatin test was first applied in filter-paper chromatography by Acher, Fromageot and Jutisz[4]. Of many known amino-acids tried, the blue colour is given only by the pyrrolidine derivatives proline and hydroxyproline, and it is surprising that this extremely useful test has not been more widely used. As described by Acher *et al.*, proline gives a blue very rapidly and hydroxyproline a somewhat fainter colour which develops rather more slowly during heating. We have found that tryptophane gives a bright rose-red colour. Other amino-acids tried (citrulline, asparagine, tyrosine, dihydroxyphenylalanine, leucine, α- and β-alanine, N-hydroxyl ethyl β-alanine, histidine hydrochloride, γ-amino butyric acid, taurine, and sarcosine hydrochloride arginine) give pink to purple colours after more prolonged heating of the isatin-sprayed paper, but the intensities of the colours are much less than those given by the pyrrolidines and tryptophane. Pyrrole does not give the blue colour. The blue isatin colour given by compound *D*1 appeared on heating almost as quickly as that given by proline and more quickly than with hydroxyproline. (3) Hydrolysis in a sealed tube at 103° C. with 6 *N* hydrochloric acid for twenty hours produced no change in the colour reactions of the compound or its position on paper chromatograms. (4) Heating with hydrogen peroxide and molybdate[5] produced no shift in its position on paper chromatograms, so that *D*1 cannot be a sulphone. (5) After dusting the paper with powdered basic copper carbonate along the line of future travel of *D*1 before running chromatograms, no spot was revealed on subsequent ninhydrin treatment[6]. The acid cannot therefore contain an amino group other than in the α-position. (6) The rate of travel of the acid in phenol is not slowed down by the presence of acetic acid instead of ammonia in the bottom of the chromatographic tank ; *D*1 is not likely, therefore, to be a basic amino-acid[6]. (7) The substance appeared to give a strongly positive test with nitroprusside in the presence of acetaldehyde—a test for a secondary amine[7]—but since it has so far been impossible to obtain the compound completely free of proline, this test is not conclusive.

*Properties of D*2. (1) It gives a blue colour with ninhydrin when run on paper, the colour changing to purple as the paper cools. The ninhydrin-treated spot fluoresces a strong magenta colour in ultra-violet light. (2) With isatin the substance gives a bright greenish-blue colour which develops immediately on heating the isatin-sprayed chromatogram. (3) The acid is unaffected by heating with 6 *N* hydrochloric acid in a sealed tube for twenty-four hours. (4) It disappears from chromatograms treated with basic copper carbonate and cannot therefore contain an amino group in other than the α-position. (5) It gives a positive test for a secondary amine[7].

As can be seen from the photomicrographs in Fig. 3, acid *D*2 crystallizes in the form of long, flat, rather feathery needles. Acid *D*1 has a somewhat similar form, but the crystals shown are from a sample contaminated with proline.

The R_F values of both *D*1 and *D*2 are shown in the table. From its reactions, including the close company it keeps with proline on ion-exchange resins and the fact that it has a higher R_F value in butanol – acetic acid – water than proline, it appears that *D*1 might well be an alkyl proline, probably methyl proline.

R_F VALUES (at 20° C.) OF VARIOUS AMINO-ACIDS IN VARIOUS SOLVENTS

Solvent*	R_F value OH-proline	Proline	*D*1	*D*2
Butanol–acetic acid–water (4 . 1 · 5 v/v)	0·19	0 30	0·44	0·42
*iso*Butyric acid–water (40 : 60 v/v)	0·41	0·60	0·71	0·67
Phenol–ammonia	0·65	0·92	0·88	0·92

* Paper equilibrated for 24 hr. with solvent-poor phase before solvent run commenced.

The elementary analysis of *D*2 was found to be: C, 55·4 per cent ; H, 8·75 per cent ; and N, 10·8 per cent. This corresponds with the formula $C_6H_{11}O_2N$. Methyl proline and the piperidine carboxylic acids have this molecular formula. Synthetic piperidine 2-carboxylic acid was prepared[8] and found to have all the properties of *D*2. Mixed melting points and a comparison of the chromatographic behaviour of the two compounds has established that *D*2 is, in fact, piperidine 2-carboxylic acid. (It has just been noted that this acid has now been isolated from beans[9].)

Apart from the interest aroused by the presence of this acid in fruits, it is surprising to find an imino-acid giving a bright purple colour with ninhydrin.

The work here described was carried out as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Extension of the *K*-Region Hypothesis of Carcinogenic Chemical Compounds

Working on suggestions put forward by Schmidt and by Swartholm, a number of French and English workers, notably A. Pullman, B. Pullman, P. Daudel, R. Daudel and C. A. Coulson, have developed a hypothesis relating the carcinogenic power of polycyclic aromatics to the structures of these compounds on the basis of quantum mechanics. Evidence has been accumulating in recent years which does indicate a fair correlation to exist between the reactivity calculated for the most reactive double bond in these molecules and their carcinogenicity. The reactive region thus supposed to be mainly responsible for neoplastic activity is usually termed the *K*-region.

Whereas the various theoretical methods used in assessing the above double-bond reactivity appeared to give fairly consistent results, some rather striking deviations were found as regards biological activity[1].

Several attempts have been made to determine double-bond reactivity by experimental means. However, both the perbenzoic acid addition method employed by Eckhardt[2] and by Boyland[3], and the osmium tetroxide addition method developed by Badger[4]—although in fair agreement with the available quantum mechanical results—again revealed several discrepancies with regard to carcinogenicity.

Being engaged in investigating the interaction of trichloromethyl radicals with various types of hydrocarbons[5], we worked out a method for the determination of the relative reactivities of these radicals towards unsubstituted polycyclic aromatics at 90° C. As recently reported[6], the rates of addition (K_R) were found to parallel the highest free valence numbers calculated for these compounds by means of the molecular orbital method. Therefore, the order of reactivities will probably be quite similar when radicals other than CCl_3 are involved, or when slightly lower temperatures are used.

Relative Reactivities of Polycyclic Aromatics towards Osmium Tetroxide (K_{OsO_4}) and towards CCl_3 (K_R)*

Compound	K_{OsO_4}	K_R	Remarks (cf. graph)
3,4-Benzopyrene	0·94	2·85	
20-Methylcholanthrene	1·1	1·95	
Cholanthrene	1·0	1·8	
Benzanthracene	0·48	1·25	
1,2-Dimethylchrysene	0·84	0·5	
2′,7-Dimethylbenzanthracene	0·62	0·21	
9,10-Dimethylbenzanthracene	2·7	0·21	
1,2,5,6-Dibenzanthracene	0·64	0·16	
Naphthacene	—†	4·4	Represented by points parallel to the K_R axis
9-Cyanoanthracene	—†	1·3	
Anthracene	—†	0·9	
Pyrene	—†	0·04	
Phenanthrene	(0·05)†	0·01	
9-Methylbenzanthracene	0·96	—‡	Represented by points parallel to the K_{OsO_4} axis
10-Methylbenzanthracene	0·91	—‡	
5,6-Dimethylbenzanthracene	0·64	—	
9,10-Diethylbenzanthracene	2·1	—§	
9-Methyl-10-cyanobenzanthracene	0·40	—	
5,6,9,10-Tetramethylbenzanthracene	2·9	—	
Acenaphthanthracene	1·1	—	

* K_{OsO_4} was determined at 37° C., K_R at 90° C.

† Not determined; judging from the low bond orders found for the most reactive 'double bonds' in these compounds, these values will be very low. Phenanthrene was found by Badger and Reed (*Nature*, 161, 238; 1948) to be about ten times less reactive towards osmium tetroxide than benzanthracene.

‡ Probably greater than 1·2 as the presence of the mesomethyl group may increase the free valence number of the opposite meso-position.

§ Probably below 0·25 (cf. 9,10-dimethylbenzanthracene).

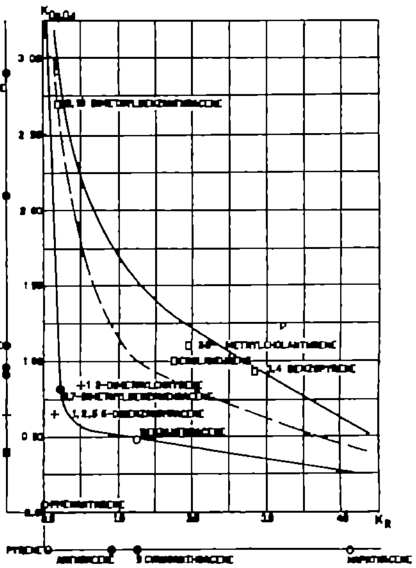

Fig. 1. □—□—, Highly active carcinogen; ●—●—, active carcinogen; +—+—, moderate activity; ○—○—, little or zero activity. (Gradings according to ref. 3)

In the course of the latter investigation, we also determined the K_R values of a number of substituted aromatics at our disposal. The results are given in the accompanying table, together with the osmium tetroxide addition-rates reported by Badger[4].

In view of the fact that several biological processes are now believed to involve homolytic rather than heterolytic reactions[7], we thought it of interest to plot K_{OsO_4} against K_R (Fig. 1).

The admittedly limited number of data would seem to suggest that carcinogenic potency depends on a quantitative relation between the two different reactivities, rather than on the *K*-region—as measured by K_{OsO_4}—alone. This supposed relationship has been illustrated in the graph by hyperbolic curves. Thus, the compounds within the region between the lower curve and the co-ordinate axes have zero or low activities, whereas the two upper curves should include a region of comparably high activity. The present data give no indications as to whether decreasing neoplastic activity will occur in the region beyond the upper curve. (However, styrene, which is inactive and which has—by definition—a K_R of 0·50[6], will probably react extremely rapidly with osmium tetroxide.)

Unfortunately, compounds which are very striking exceptions to the relation between carcinogenic power and *K*-region activity, such as acenaphthanthracene and 9-methyl-10-cyanobenzanthracene (cf. footnotes in the table), were not available to us. On the other hand, the very low activity of 2′,7-dimethylbenzanthracene and the high potency of the cholanthrenes and of 3,4-benzpyrene, which is comparable to that of 9,10-dimethylbenzanthracene, cannot be well correlated on the basis of the *K*-region activity alone. In accordance with the conclusions of Magat and Bonême based on the inhibition of thermal polymerizations of styrene by carcinogens[8], there appears to be no direct relation between neoplastic activity and reactivity towards radicals.

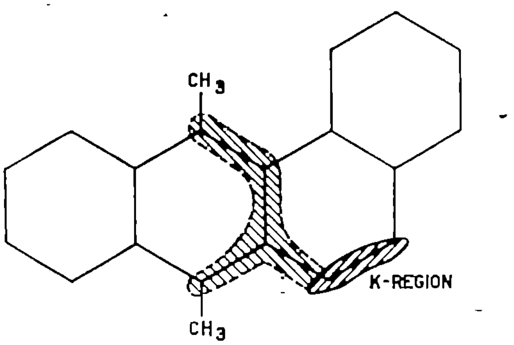

Fig. 2 Supposed reactive region in 9,10-dimethylbenzanthracene, including the reactive meso-positions and the *K*-region

From a theoretical point of view, the above extension of the *K*-region hypothesis implies a relationship between carcinogenic potency, on one hand, and the highest free valence number and bond order (or excess of charge[1]), on the other. As the positions of highest free valence number scarcely ever coincide with one of the atoms of the most reactive double bond[1], this suggests that a larger part of the molecule is involved in the carcinogenic mechanism than the *K*-region alone (Fig. 2). (According to the molecular orbital method, the free valence number of a given atom is obtained by subtracting the sum of the bond orders of the bonds terminating at that atom from a constant which is characteristic for that atomic species and its binding type[9].)

It may be remarked that such a possibility was recently mentioned by Boyland[1]; his interesting hypothesis, however, deals with structural properties of carcinogens rather than with different types of reactivity.

The requirement of two different types of reactivity within a single molecule suggests possibilities for interpretation or experimental attack as regards combination or inhibition effects; for example, by studying the biological effect of a potent carcinogen admixed with a non-carcinogenic compound having a high K_{OsO_4}. Strong evidence for the existence of these effects has been given by Lacassagne *et al.*[10].

In conclusion, it is emphasized that the above speculation ensued as a sideline from fundamental work on hydrocarbons in progress in this laboratory. Thus we have not attempted any detailed verification; our main intention is to direct attention to a number of data which may suggest that free radical reactions play a part in a field of such widespread interest as carcinogenesis.

Carbohydrate Residue of a Urine Mucoprotein inhibiting Influenza Virus Hæmagglutination

The first step in the propagation of influenza virus is the adsorption of the infective particle on to the receptor substance at the surface of the host cell. Human, guinea pig and fowl erythrocytes, though not susceptible to infection, possess analogous receptors which, by allowing virus particles to form 'bridges' between cells, give rise to the hæmagglutination characteristic of influenza viruses[1]. A variety of soluble mucoids, by competing with the cellular receptors for the virus, inhibit hæmagglutination[2]. There is much indirect evidence to suggest that the receptors and the soluble mucoids have some basic structure in common, that this common structural feature is predominantly of carbohydrate nature and that the carbohydrate is instrumental in the attachment of the virus to the cell receptors and their mucoid analogues[1]. In fact, the inactivation by living virus of the capacity of a mucoprotein to inhibit hæmagglutination by indicator virus is accompanied by the release of a sugar derivative characterized as an N-substituted fructosamine[3].

The availability of a pure mucoprotein from urine[4] inhibiting the virus hæmagglutinin to a high titre rendered possible an investigation of its carbohydrate residue. With this mucoprotein prepared by a modified technique[5], three series of experiments were performed:

(1) *Acid hydrolysis*: (*a*) *Simple sugars*. The hydrolysate from acid treatment (1 *N* sulphuric acid, 100°, 4½ hr.), after removal of the acid as barium salt, was dialysed at 4° against 10 volumes of water. The concentrated dialysate was analysed qualitatively and semi-quantitatively[6] by paper-partition chromatography (descending), using butanol/acetic acid/water (40 : 10 : 50) and *s*-collidine as solvents and aniline hydrogen phthalate as spraying agent. The results were as follows: 5·4 per cent galactose, 2·7 per cent mannose, 1·0 per cent fucose. The fucose content of the untreated mucoprotein, estimated spectroscopically by courtesy of Prof. Z. Dische, of New York, was found to be 1·1 per cent. Xylose present in traces (about 0·04 per cent) may be regarded as an artefact. (*b*) *Amino sugars*. The hydrolysate (2 *N* hydrochloric acid, 100°, 14 hr.) contained 7·6 per cent hexosamine (base), as determined colorimetrically[7]. From chromatographic evidence it would appear that the hexosamine is a mixture of glucosamine and galactosamine (run in *s*-collidine at 4°, sprayed with Ehrlich reagents). This identification is based on: (i) the identity in R_F value and colour of the two assay spots with the spots given by the glucosamine and galactosamine standard respectively; (ii) the positive ninhydrin reaction of the two assay spots; and (iii) the observation that addition of a glucosamine–galactosamine mixture to the hydrolysate resulted in an intensification of the pre-existing spots but not in the appearance of further ones.

(2) *Periodate oxidation*. When the mucoprotein was treated with an excess periodate (0·01 *M* potassium periodate, *p*H 5·0, 20°, 24 hr.), followed by acid hydrolysis, neutralization and dialysis as under (1), half the galactose and mannose, a fraction only of hexosamine and none of the fucose were recovered.

(3) *Alkaline treatment*. By treatment of the mucoprotein with 10 per cent barium hydroxide at 100° for 12 hr., the carbohydrate complex may be separated

from the bulk of the protein. After removal of the insoluble residue and concentration of the supernatant, the polysaccharide was precipitated by 66 per cent ethanol; on acid hydrolysis it yielded galactose, mannose, fucose and hexosamine. This hydrolysis was accompanied by the formation of considerable amounts of soluble and insoluble humin matter, suggesting the presence in the polysaccharide of the component released from the mucoprotein by viral enzyme action[3]. The polysaccharide is dialysable through 'Cellophane' casing.

From these observations, it may be concluded that the smallest carbohydrate unit in the mucoprotein consists of approximately six hexosamine, four galactose, two mannose, one fucose residue(s) and probably of another minor component corresponding to the molecular weight of about 2,500 (assuming N-acetylation of the hexosamine residues) or a multiple *n* thereof, if the smallest unit contains more than one fucose residue. However, the dialysability of the polysaccharide obtained from the mucoprotein by alkali treatment or, in preliminary experiments, by tryptic digestion, would suggest that *n* is not more than 3 or 4; crystalline lysozyme (mol. weight 16,000) in a buffer solution of *p*H 6·0 passes through the membrane to a minute degree only. Therefore the smallest unit $(2,500)_n$ may be regarded as a complete prosthetic group rather than the repeating unit of a giant polysaccharide. The mucoprotein, then, is visualized as a conjugated protein containing as prosthetic group a relatively small polysaccharide; about two hundred of such groups may be linked to each protein molecule (on the basis of 7×10^6 mol. weight[4]). This concept is consistent with the biological[8] and biochemical[9] data. It seems of considerable interest that the carbohydrate moiety of the receptor substance present at the surface of human erythrocytes consists of glucosamine, galactosamine, galactose and fucose[6], though only further work with periodic acid will reveal any common structural features of the identical components of the cellular receptors and their soluble analogues.

Prof. G. Blix, University of Uppsala, kindly informed me that his laboratory is also engaged in an analysis of the carbohydrate residue of the urine inhibitor, and we agreed to submit to *Nature* simultaneously but independently a summary of our results.

IN a study carried out in this Institute on the polysaccharides of normal human urine, particular attention was paid to the urinary mucoprotein reported to inhibit influenza virus hæmagglutination[1].

The inhibitory substances to be reported here were prepared in three different ways. (1) A preparation was made by the method of Tamm and Horsfall[1], by precipitating urine with ethanol. The precipitate was dissolved in water and shaken with chloroform–amyl alcohol. The interfacial precipitate was redissolved in water, dialysed, and dried by lyophilization. (2) Diluted urine was precipitated by addition of sodium chloride to a concentration of 0·58 *M*, according to the method of Tamm and Horsfall[2]. By this means, these authors obtained an electrophoretically homogeneous, very strongly inhibiting product. No details about its carbohydrate components were given. (3) Urine was centrifuged for 15 min. at 45,000 r./min. in a Sharples supercentrifuge. The precipitate was dissolved in distilled water, washed with 0·58 *M* sodium chloride, and dialysed. The solution was then centrifuged for one hour at 22,000 r./min. and the supernatant lyophilized. All three preparations are strong inhibitors of hæmagglutination and show about the same activity.

Some of the analytical results are given in the accompanying table.

Component	Amount in preparation (per cent)		
	1	2	3
Hexosamine	6·4	9·4	7·0
'Sialic acid'	8·2* 7·3†	0·2* 9·1†	0·4* 9·1†
Hexose	6·8	8·4	9·0
Fucose	0·7	1·1	1·1
Nitrogen	11·2	10·9	10·7
Phosphorus	—	0·09	0·16
Sulphate sulphur	—	0·4	0·8

* 'Direct' Ehrlich reaction (ref. 3). † Bial's reaction (ref. 3).

In addition to the quantitative determinations given in the table, the following analysis was carried out. Preparation 2 was hydrolysed and studied by paper-partition chromatography. Spraying with aniline phthalate indicated the presence of galactose, mannose, and a small amount of fucose. With ammoniacal silver nitrate as spraying reagent, the presence of hexosamine was also indicated.

The analytical results indicate that the inhibitory mucoprotein contains, in addition to 'sialic acid', carbohydrate of the glucosamine–mannose–galactose type commonly occurring in proteins, and a small amount of carbohydrate of the type occurring in blood-group substances.

The name 'sialic acid' has recently[4] been given to a monobasic reducing acid with the probable composition $C_{14}H_{24}NO_{11}$, which was first isolated in crystalline form from submaxillary mucin in 1936[5]. Its structure is still unknown. It is characterized by strong humin formation and liberation of carbon dioxide on heating with mineral acid. It gives a purple colour even without previous treatment with alkali on heating with Ehrlich's *p*-dimethylaminobenzaldehyde reagent, and a violet colour when treated with Bial's orcinol reagent. Judging from these reactions, sialic acid or closely related substances are widely distributed in the animal organism[7]. Sialic acid seems to be regularly accompanied by chondrosamine[4].

From observations made in a study of the dialysable product split off by the action of influenza virus on the inhibitory urinary mucoprotein, Gottschalk[8] concluded that the carbohydrate component involved in this reaction has the structure of *iso*glucosamine. He defined the split product as N-1-deoxy-1-ketose amino-acid (lysine ?) or peptide. It is not yet clear what relation Gottschalk's product bears to sialic acid. (Preliminary experiments, however, indicate that a substance obtained by Gottschalk's procedure gives the colour reactions characteristic of sialic acid.)

Inhibitory products obtained by us from egg-white, ovomucin[7], allantoic fluid[8], ovarian cysts[8], follicular fluid from cows[8], and cancer fluid[8], were all found to contain sialic acid. Both the cancer fluid and the contents of one of the cysts showed very strong inhibitory activity, and no other carbohydrate (except hexosamine) was found to be present in appreciable amounts. This might suggest that sialic acid is of fundamental importance for the inhibitory reaction and may bear some relation to the receptor substance of erythrocytes. This suggestion is supported by the fact that a great many materials reported in the literature as containing hæmagglutination inhibitors have also been found to contain sialic acid; for example, blood serum, some plasma glycoproteins[4], human tears[9], cow's milk[4], epithelial mucins of various origins[9], human saliva[9], and meconium[9]. No quantitative relation, however, has been found between the content of sialic acid and the inhibitory activity of the different products examined. Thus a preparation of submaxillary mucin from cattle has a high content of sialic acid but a very low inhibitory activity, whereas allantoic fluid has a low sialic acid content and a high activity. Pure sialic acid has no activity at all.

It is then evident that if substances giving the characteristic reactions of sialic acid are concerned in the inhibition of virus hæmagglutination, either finer structural differences in the carbohydrate group or the properties of the accompanying protein component must be the determining factors for the inhibitory activity.

It was agreed with Dr. A. Gottschalk, of the Walter and Eliza Hall Institute of Medical Research, Melbourne, who is also investigating the carbohydrate components of the hæmagglutination-inhibiting mucoprotein from urine, to submit to *Nature* independently but simultaneously a summary of our results.

Indicator Spray for Amino-Acids

IN quantitative one-dimensional paper chromatography of amino-acids, the position of the various bands is generally determined either by running reference strips on the edges of the paper or by spraying lightly with weak ninhydrin solution. Neither method is entirely satisfactory. Reference strips are not always a reliable guide to cutting, particularly if the bands are close together, since the fronts may not be straight; the use of ninhydrin must give rise to some loss, which will fall most heavily on the acids present in least amount.

In this laboratory, we determine the individual acids manometrically following oxidation, and have developed an indicator spray which shows the position of the bands and does not interfere with the subsequent analysis. The spray consists of an alkaline alcoholic solution of bromothymol blue incorporating formaldehyde, so that, on the principle of the formol titration, the amino-acids appear as acid (yellow) bands against an alkaline (blue) background. The paper gradually fades to a uniform yellow colour; but the bands can, if necessary, be marked with a ball-point pen for subsequent cutting.

The spray has been used successfully for some time now, generally following a neutral solvent such as propanol–water, so that there is no trouble from residual acidity or alkalinity on the paper which, for quantitative work, is air-dried without application of heat. The spray solution is prepared by adding 3 ml. formalin and 0·1 ml. 60 per cent aqueous potassium hydroxide to 20 ml. 0·15 per cent (w/v) solution of bromothymol blue in 95 per cent alcohol.

The indicator appears to be almost as sensitive as ninhydrin, particularly for the shorter-chain amino-acids; but the bands tend to be somewhat narrower, and, when cutting for quantitative work, a little of the paper on either side of the band should be included.

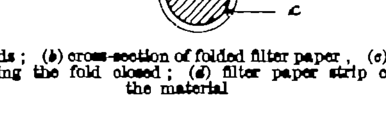
Application of Material in Filter Paper Chromatography

IN order to obtain a good separation in filter paper chromatography, the size of the spot of liquid applied to the paper must be small, which often necessitates repeated, time-consuming applications of material. Methods have been evolved with the purpose of having spots or a band laid down automatically by a burette[1,2]. There still seems to be a need, however, for a technique by which a larger volume of fluid can be deposited quickly and simply, yet permitting small-sized bands or spots for good separation.

We have used the following procedure. The fluid material is deposited on a strip of filter paper 2–5 mm. in width according to the degree of separation wanted. The filter paper strip, after drying, is placed in a z-shaped fold of the filter paper sheet. The size of the fold is slightly larger than the strip (see diagram). In this way the strip carrying the substance to be chromatographed is covered by the filter paper sheet on both sides. The fold is kept closed by the application, on each side of the sheet, of glass rods ground plane on one side or by glass plates of some 5 mm. width and 1·5 mm. thickness. The glass rods or plates are held together on each side of the paper with rubber bands exerting a slight pressure. The filter paper strip should not reach the margin of the sheet but leave 0·5–1 cm. on each side.



(*a*) Glass rods; (*b*) cross-section of folded filter paper, (*c*) rubber band keeping the fold closed; (*d*) filter paper strip carrying the material

The filter paper strip can, according to its size, absorb an amount of fluid of 5–10 c.mm. per cm. at each application. After drying, additional amounts of fluid can be applied.

In order to facilitate application of a total of 0·5–1 ml. fluid on a filter paper strip, the strip is placed on the flat floor of a small 'Lucite' trough holding 1–2 ml. and with sloping walls. The solution is easily dried up on the paper in the desiccator. It is preferable to treat the trough and glass plates with some anti-wetting compound. In this way a given extract concentrated to a suitable volume can be absorbed quantitatively by the strip, dried and subjected to chromatography in a short time.

The separation is satisfactory if a filter paper strip (2·5 mm. × 40 mm.) which has absorbed in one stage 0·02 ml. of a solution containing 1 mgm. adrenaline and 1 mgm. noradrenaline per ml. (ascending run, 15 hr. in phenol/0·1 *N* hydrochloric acid) is used.

The method has proved adequate with Grycksbo *OB* paper, but is not suitable for the harder papers such as Whatman No. 1 or 4.

We have found no difference in result if the paper strip is placed in one or the other of the two folds.

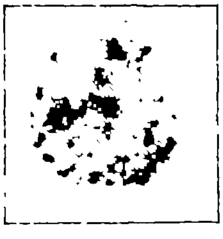
Demonstration by Radioactive Tracers of the Adsorption of Cations by Metals

The electromotive force of a primary electric cell is still explained by Nernst's theory, which only considers the case of a metal and its own cations. We have developed a more general theory[1], based on the hypothesis that the electrode potentials are due to the adsorption of cations. To emphasize the difference between the two theories, it is only necessary to say that, according to our view, all the individual potentials ought to be negative.

Experiments carried out in our laboratory, which will be published in due course, show that every metal has a selective adsorption power in the sense that if the electrolyte contains several kinds of cations, though all of them contribute to the potential of the electrode, only the active ones are adsorbed. It seems, moreover, that in some cases ions from the metal go into the solution and are replaced by an equivalent number of active cations.



Autoradiograph of an aluminium foil after 12 days immersion in a 0·27-*M* solution of activated zinc sulphate. It shows that only isolated domains are active. Similar results have been obtained with copper, lead, iron and nickel

The direct proof for the exchange of cations has been obtained with radioactive tracers. A sample from the Atomic Energy Research Establishment, Harwell, containing 5 gm. of irradiated zinc converted into zinc sulphate, with an activity of 7 mC. due to zinc-65, was diluted so as to obtain a solution of 0·27 molarity. Metals in the form of wires, of about 25 mm. length and 0·55 mm. diameter, were immersed in separated portions of such a solution and, after thorough washing, were tested with a Geiger–Müller counter, with the aid of a sample changer which makes it possible to reproduce the geometrical conditions very accurately. Table 1 shows the results, corrected for the background counting rate, after 7 days immersion.

Table 1

Metal	Pt	Pd	Au	Ag	Cu	Fe
Counting-rate per min	15	128	241	330	159	889

The effect, which is rather small with platinum, becomes very striking with all other metals. We consider this result as a proof that in the first case there is pure adsorption, whereas in the second, adsorption is followed by exchange of cations.

With foils instead of wires, it has been possible to compute the total number of atoms of zinc, radioactive and not radioactive, taken by each square centimetre. The results obtained with lead are given in Table 2. Copper and nickel have shown similar behaviour.

Table 2

Concentration	Time of Immersion	Atoms per sq. cm.
0·27 *M*	1 hr.	4·1 × 10^{14}
"	22 hr.	11·3 "
"	22 days	8,800 "
0·0027 *M*	22 hr.	7·5 "
"	22 days	200 "

Autoradiographs obtained with foils activated by immersion in the solution of radioactive zinc show that the exchange of cations takes place in small and separated portions of the surface; thus, the so-called local effect has been made visible.

Ion-Exchange Elution Series

A comparison of the efficiency of various eluants in ion-exchange separations of the lanthanons[1] has led to the hypothesis that the relative values of eluants (and the optimum conditions of their employment) may be simply related to the overall stability constants of the complexes formed between the lanthanon ions and the eluting agent.

Comparison of eluants apart, however, the argument entails that the sequence of stability values ($\log \overline{K}$) of lanthanum eluant complexes should coincide with the elution sequence. This has been confirmed not only for tervalent lanthanon ions but also for bivalent metal ions. However, in systems of mixed bi- and ter-valent ions, although the elution sequence for ions of the same charge remains the same, the elution series of the mixed ions is out of conformity with the stability series for the mixed ions. Thus, the stability series for ethylenediamine tetra acetic acid complexes is[1,2]:

Ion	log $\overline{K}$	Ion	log $\overline{K}$	Ion	log $\overline{K}$
Yb^{3+}	18·70	Sm^{3+}	17·20	Co^{2+}	16·10
Ni^{2+}	18·45	Nd^{3+}	16·75	Ce^{3+}	16·05
Cu^{2+}	18·38	Pr^{3+}	16·55	La^{3+}	15·30
Pb^{2+}	18·20	Cd^{2+}	16·48	Fe^{2+}	14·22
Er^{3+}	18·15	Zn^{2+}	16·15	Mn^{2+}	13·47
Y^{3+}	18·00				

The elution sequence, however, is:

Ni, Cu, Yb, Y, Dy, Cd, Eu, Zn, Sm, Co, Fe, Nd, Mn, Pr, La[1].

Similarly, with nitrilotriacetic acid complexes, some log $\overline{K}$ values are:

Cd, 9·54; La, 10·37; Pr, 11·7; Sm, 12·4.

Fitch and Russell[3] find that cadmium is interpolated between neodymium and samarium. These interpolations, of manganese between praseodymium and neodymium, and of cadmium between neodymium and samarium, while of great use in lanthanon separations[1,2], introduce two possible amendments to the case for a simple relationship of stability constants and eluant efficiencies: (*a*) that the stability series determined through potentiometric titrations of the complex system do not hold in ion-exchange systems, because of the formation of different complex species; or (*b*) that the stability series varies because of a factor influenced by the valency of the ions.

Since log $\overline{K}$ values are overall constants and take account of a multitude of complex species, alternative (*a*) is scarcely tenable. An examination of the second factor has, however, confirmed that a preponderance of tervalent ions induces an apparent increase in the stabilities of bivalent ion complexes and vice versa. Thus, with ethylenediamine tetra acetic acid solutions as the eluant, the experimentally determined series are as follow:

With preponderance of bivalent ions:
Yb, Er, Ni, Cu, Sm, Nd, Pr, Ce, La, Cd, Co, Fe, Mn.

With preponderance of tervalent ions:
Ni, Yb, Y, Cd, Eu, Zn, Sm, Fe, Nd, Mn, Pr, La.

With equivalence of bi- and ter-valent ions:
Yb, Ni, Pb, Er, Sm, Nd, Pr, Cd, Co, La, Fe, Mn.

This phenomenon does not appear to have been recorded hitherto and is being further studied.

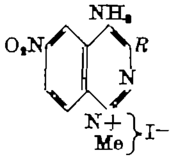
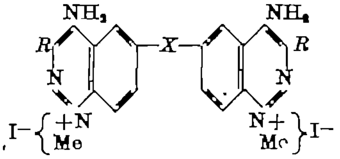
Reduction of Nitrophenanthridinium Salts: Influence of Molecular Size on Trypanocidal Activity

In 1948 Kenneford, Lourie, Morley, Simpson, Williamson and Wright[1] reported that the crude reduction products of the cinnolinium salts (I; *R* = H or Me) showed considerable activity in infections of *Trypanosoma congolense* in mice, whereas the pure diamino-salts were inactive. They attributed this phenomenon to the probable presence in the crude products of azo-compounds (II; *X* = —N=N—) of high trypanocidal activity. It has recently[2] been further demonstrated that structures of the general formula (II), where *X* may have values other than —N=N—, have trypanocidal properties, the most effective being '528' (II; *R* = H, *X* = $-\mathrm{NH.}\underset{\underset{\mathrm{NH}}{\|}}{\mathrm{C}}\mathrm{.NH}-$).

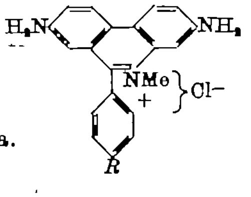


(I)

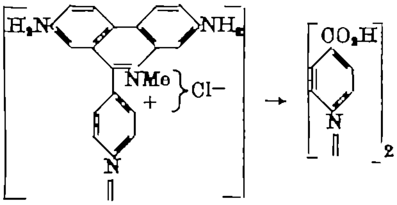


(II)

One of us (L. P. W.) has long used iron powder for the reduction of nitrophenanthridinium salts in aqueous solution to amino-salts, and has observed[3] that sparingly soluble by-products are frequently formed, although usually in very small amount. In the reduction of 2-amino-10-methyl-9-*p*-nitrophenylphenanthridinium chloride, however, a crystalline by-product was isolated[4], and the reduction of 2 : 7-diamino-10-methyl-9-*p*-nitrophenylphenanthridinium chloride (III; *R* = NO_2) by iron – water is so unsatisfactory that this reagent was replaced by ferrous hydroxide – water[5], which is a much better reagent for the reduction of nitro-quaternary salts. In 1949, a quantity of the powerful trypanocide (III; *R* = NH_2) was required for field trials, and we decided to re-examine the iron – water reduction of (III; *R* = NO_2).



(III)



(IV) (V)

When a hot aqueous solution of 70 gm. of (III; *R* = NO_2) was stirred with iron powder (70 gm.; "reduced with hydrogen"), 49 gm. of a sparingly soluble substance was isolated. It separated from its purple solution in hot water as a gel, which slowly changed to a mass of microscopic black plates, but crystallized from methanol in black prisms, which are purple by transmitted light, unmolten at 350°. A small quantity of (III; *R* = NH_2) was isolated with difficulty. The new substance is undoubtedly the azo-salt (IV) (found for dried salt: C, 69·4; H, 4·85; N, 16·0; Cl, 10·4. $C_{40}H_{34}N_8Cl_2$ requires C, 68·9; H, 4·9; N, 16·1; Cl, 10·2 per cent). Its light absorption resembles that of (III; *R* = NO_2) rather than that of (III; *R* = NH_2), supporting the presence of the chromophore —N=. It was oxidized readily in aqueous solution by permanganate, affording a good yield of 4 : 4′-azobenzenedicarboxylic acid (V), which was identified as its ethyl ester with an authentic specimen. Under similar conditions (III; *R* = NO_2) gave 4-nitrobenzoic acid. The azo-salt is converted by dilute hydrochloric acid into a crystalline rust-coloured hydrochloride, which is rapidly hydrolysed by water or alcohol to the original salt.

There appears to be no adequate analogy to the facile reduction of a nitro- to azo-compound, which occurs in this and presumably the cinnoline series, and the explanation is probably to be found in the fact that both reactant and product are present in aqueous solution. The azo-compound is unlikely to be an intermediate in the reduction to amine, for it is highly resistant to further reduction. More probably the nitroso-compound is intermediate and, if it is not itself rapidly reduced further to amine, condenses with amine already present. The proportion of amine (III; $R = NH_2$) formed appears to increase at the expense of (IV) as the efficiency of stirring improves, and this suggests that for reduction of (III; $R = NO_2$) to (III; $R = NH_2$) an adequate concentration of ferrous ions is required throughout the reaction solution. With a colloidal suspension of ferrous hydroxide this condition is more likely to be fulfilled, and (IV) is therefore not produced. This explanation is, of course, incomplete in that it does not account for the great variation of yield of azo-salt from different nitro-quaternary salts.

In view of the results of Lourie and his collaborators and the known efficacy of 'double' molecules as trypanocides[1], our biological results with (IV) are of considerable interest. Against *T. congolense* in mice it is only one-hundredth as active as either (III; $R = NO_2$) or (III; $R = NH_2$), these results being in striking contrast to those obtained by 'doubling' the aminoquinoline or aminocinnoline molecules. On the other hand, it exerts a more prolonged prophylactic action in mice than any other phenanthridinium salt we have examined, and its toxicity by the subcutaneous route is low, mice surviving a subcutaneous dose of 1 gm. per kgm. body-weight for ten days. These results suggest slow absorption, perhaps due to depot formation; but other properties of (IV) do not necessarily support such an explanation. Thus its solubility in water (6 gm. per litre at 20°) is practically the same as that of (III; $R = NO_2$), and its activity against *T. rhodesiense* in mice amounts to one-third of that of (III; $R = NH_2$), which is the most active member of the series yet known against this species. Thus against *T. rhodesiense* the activity of (IV) ranks high in the series[6]. That (IV) separates from aqueous solution as a gel suggests that the solution is colloidal, and it is significant that the notable prophylactic properties of suramin, which also is a large molecule, have been attributed *inter alia* to the colloidal nature of its solution. It is possible also that (II) and (III) represent optimum molecular patterns for *T. congolense* activity, and that the area of the molecules is critical.

Relation between Intrinsic Viscosity and Degree of Polymerization

It is generally agreed that the relation between intrinsic viscosity and degree of polymerization (D.P.), for the majority of polymer systems, is of the form $[\eta] = K\,(\text{D.P.})^{\alpha}$; but there appears to be no slackening in the controversy as to the numerical values of K and α for a particular system. Most of the values have been obtained from measurements of the intrinsic viscosity and osmotically determined degree of polymerization on nearly homogeneous fractions. Apart from experimental error, there is a number of ways in which discrepancies can arise. High intrinsic viscosities may not be free from the influence of the non-Newtonian behaviour of the solutions from which they are derived; fractions may not be sufficiently homogeneous; and membranes may not be strictly semi-permeable[1].

There is, however, an additional source of error, more often than not neglected. It has been pointed out[2] that in osmometry the osmotic pressure in cm. of water is not simply the difference in height between the menisci of the solution and solvent, multiplied by the density of the solution; it is actually the difference in pressure between the column of solvent and the column of solution, when the column length is measured from the centre of pressure of the cell, in the case of a vertical membrane, or from the membrane, when it is horizontal, to the meniscus. For dilute solutions, the correction to be added requires an approximate measurement of the vertical distance between the solvent meniscus and the centre of the membrane, and a knowledge of the densities of the solvent and solution.

The correction is much larger for the Fuoss–Mead[3] than for the Schulz[4] osmometer. For a solution of given concentration in a particular osmometer, the correction to the osmotic pressure is of the same order whatever the degree of polymerization of the solute. The effect on the absolute value of the osmotic pressure is then greatest for solutes of high degree of polymerization, and hence the relation between intrinsic viscosity and degree of polymerization is altered.

The relation between the intrinsic viscosity (dl./gm.) in butyl acetate at 25° C., and the degree of polymerization, measured in an osmometer of the Fuoss–Mead type, has recently been determined in these laboratories for a series of fractions of cellulose nitrate, containing 14 per cent of nitrogen, derived from viscose rayons and covering the range of degrees of polymerization from 100 to 1,800. The uncorrected values for K and α were 0·0154 and 0·93 respectively, but on making the correction they became 0·0108 and 1·0. This startling change stresses the importance of the density of the solution in osmotic pressure measurements.

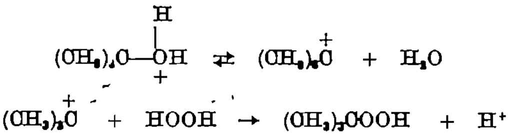
Preparation of Alkyl Hydroperoxides

Alkyl hydroperoxides have been prepared by the action of hydrogen peroxide on: (1) alkyl sulphates, R_2SO_4, in the absence (for example, R = Bu^t)[1] or presence (for example, R = Et)[2] of alkali; (2) tertiary alcohols in the presence of a trace of concentrated sulphuric acid[3]; (3) triphenylmethyl halides[4,5]. All these reactions may be interpreted as involving nucleophilic attack of the HOOH molecule or HOO^- ion on a carbon atom according to the general equation:

$$HO\ddot{\underset{..}{O}}{:} + CR_3{-}X \rightarrow HOO{-}CR_3 + \bar{X}.$$

Both oxygen atoms in the resultant peroxide thus originate in the hydrogen peroxide molecule. This must necessarily be the case in reaction (3), but it is also thought to apply in reactions of types (1) and (2). The reaction may proceed by either of the two established mechanisms of nucleophilic substitution (the S_N1 and S_N2 mechanisms), and variation in constitutional and environmental factors will produce the usual effects[6]. Characteristic stereochemical consequences may be expected; for example, partial or complete racemization should accompany mechanism S_N1.

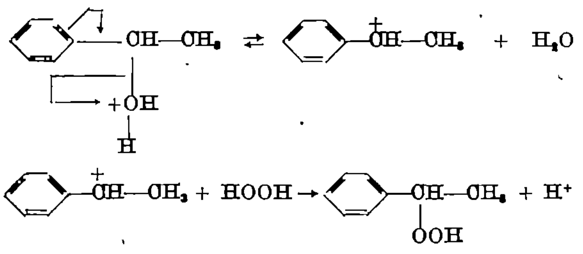
Criegee and Dietrich[3] state that primary and secondary alcohols do not react under the conditions of reaction (2). This reaction probably occurs readily with tertiary alcohols because inductive and hyperconjugative electron release by the alkyl groups, in conjunction with acid catalysis, facilitates the production of a carbonium ion which is then attacked by the hydrogen peroxide to give the alkyl hydroperoxide (the S_N1 mechanism).



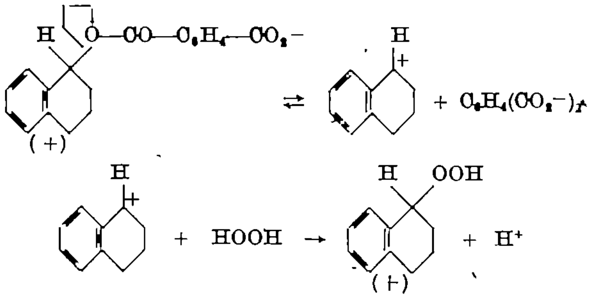
$$(CH_3)_3C{-}\overset{H}{\underset{+}{O}}H \rightleftharpoons (CH_3)_3\overset{+}{C} + H_2O$$

$$(CH_3)_3\overset{+}{C} + HOOH \rightarrow (CH_3)_3COOH + H^+$$

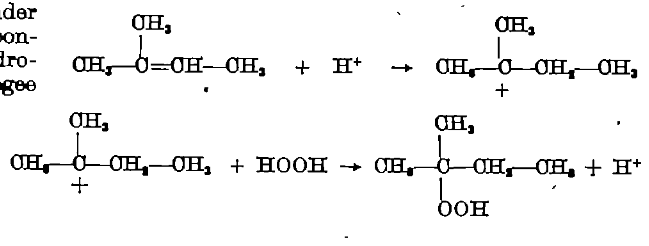
The reaction should, therefore, not be restricted to tertiary alcohols, but should apply to any alcohol which will yield carbonium ions under the conditions of reaction. This has been confirmed by the preparation of 1-phenylethyl hydroperoxide from 1-phenylethyl alcohol under Criegee and Dietrich's conditions. In this case, the S_N1 reaction is facilitated by electron release by the phenyl group; in *sec.*-butyl alcohol this factor is absent, and this alcohol is unreactive under the same conditions[7].



Hydroperoxides should also be produced by other types of compounds which are capable of the production of alkyl cations. Thus a carboxylic ester which readily undergoes alkyl–oxygen fission should be perhydrolysed to give an alkyl hydroperoxide and a carboxylic acid. This reaction has been established in the case of the hydrogen phthalate of 1 : 2 : 3 : 4-tetrahydro-1-naphthol. This ester has been shown to have a tendency to react by an alkyl–oxygen fission mechanism: for example, the optical activity of the alcohol obtained by hydrolysis of the ester decreases with decreasing nucleophilic power of the hydrolytic reagent, and the alcohol itself readily forms a sulphone with *p*-toluenesulphinic acid[8]. It has now been found that when 1 : 2 : 3 : 4-tetrahydro-1-naphthyl hydrogen phthalate is dissolved in 90 per cent hydrogen peroxide containing sodium bicarbonate, 1 : 2 : 3 : 4-tetrahydro-1-naphthyl hydroperoxide, identical with the product obtained by the autoxidation of 1 : 2 : 3 : 4-tetrahydronaphthalene, soon separates in good yield; if the optically active ester is used, the inactive hydroperoxide results. It has been shown that 1 : 2 : 3 : 4-tetrahydro-1-naphthol does not react under similar conditions and thus cannot be an intermediate in the reaction. The reaction would therefore appear to proceed by a unimolecular alkyl–oxygen fission mechanism, as follows:



The addition of a proton to an olefine will also produce an alkyl cation, which should react with hydrogen peroxide to lead to the formation of an alkyl hydroperoxide. This has been confirmed in the case of 2-methylbut-2-ene. This olefine, when stirred for 18 hr. with 90 per cent hydrogen peroxide in the presence of a trace of concentrated sulphuric acid, gives a good yield of *tert.*-amyl hydroperoxide. The mechanism of this reaction is hence thought to be as follows:



$$CH_3{-}\overset{CH_3}{C}{=}CH{-}CH_3 + H^+ \rightarrow CH_3{-}\overset{CH_3}{\underset{+}{C}}{-}CH_2{-}CH_3$$

$$CH_3{-}\overset{CH_3}{\underset{+}{C}}{-}CH_2{-}CH_3 + HOOH \rightarrow CH_3{-}\overset{CH_3}{\underset{OOH}{C}}{-}CH_2{-}CH_3 + H^+$$

Nature of the 'Induction Period' in the Preparation of Lithium Aluminium Hydride

FOR the preparation of lithium aluminium hydride, Schlesinger *et al.*[1] claim that an addition of lithium aluminium hydride to the ether covering the powdered lithium hydride is essential. In absence of it a smooth reaction between lithium hydride and aluminium chloride was not always possible, and a period of induction ranging from a few minutes to several hours followed. Such induction periods were undesirable as they made the reaction uncertain and also difficult to control once it began again. To overcome this difficulty, Schlesinger *et al.* give two elaborate methods for making lithium aluminium hydride for subsequent catalytic use. These methods unfortunately involve complicated apparatus which is difficult to find, if at all, in most laboratories.

Thus when making lithium aluminium hydride, owing to the non-availability of lithium aluminium hydride for catalytic purposes, the reaction was tried without the addition of lithium aluminium hydride to ether covering powdered lithium hydride. It was noticed that the reaction always started immediately and continued smoothly to the end. In view of these observations it was difficult to understand the difficulty encountered by other authors until the following clue was obtained.

Once, while making lithium aluminium hydride by the usual method (that is, without the addition of lithium aluminium hydride), the reaction failed to start and an induction period lasting for twelve hours followed. When the reaction was conducted on a portion of lithium hydride from the same source, but with an addition of lithium aluminium hydride to ether covering it, the reaction went smoothly. This proved conclusively that there was something in ether that was responsible for the induction period and that it was removed or destroyed by lithium aluminium hydride. A portion of the ether was therefore distilled over lithium aluminium hydride and then used in the preparation of hydride. The reaction went smoothly. The same effect was produced when ether was carefully dried again over sodium. In view of these results, it was clear that the induction period was caused by inactivation of lithium hydride powder, probably by water that remains in ether when not thoroughly dry. This view fits in well with the fact that, whereas sodium wire takes a long time to remove the last traces of moisture owing to its surface reaction alone, lithium aluminium hydride, by virtue of its solubility in ether, can remove moisture spontaneously on mixing. The inactivation of lithium hydride may therefore lie in the formation of a protective film, probably of lithium hydroxide, on the surface of its particles, and the induction period may well be the time required to remove this film by chemical and mechanical means. Once this unreactive coating is removed, a vigorous reaction is conceivable in presence of a large amount of aluminium chloride in ether.

In view of these observations, it can be stated that it is desirable to add lithium aluminium hydride for catalytic purposes; but in absence of it, a smooth reaction can be ensured by using carefully dried ether.

Intensification of the Latent Photographic Image produced by Beta-Rays

IT is known that a latent image produced by a brief exposure to light can be intensified by a post-exposure to light of low intensity. This fact can be explained by assuming the production of a non-developable latent sub-image in addition to the normal latent image which can be developed. The latent sub-image can be converted to a developable latent image by a carefully controlled post-exposure to light of low intensity.

As the photographic action of charged particles on an emulsion is basically the same as that of light, it is to be expected that a latent sub-image is also produced by these particles. It is also to be expected that this latent sub-image would be produced in quantity when a fine-grain emulsion is exposed to fast particles of low charge, for example, if β-rays fall on plates which are not very sensitive to these rays.

We had available Kodak *NT* 2 *A* plates and a source of 0·01 μC. radium-D from the Atomic Energy Research Establishment, Harwell. This source was filtered by 10 mgm./cm.^{2} aluminium, so that only the β-rays from radium E were effective. The middle part of the plates was exposed to the β-rays for 1–2 days. After this exposure, half the plate was exposed to light from a 6·5-V. 0·2-amp. lamp at a distance of 2 m. for 20–28 sec. The plates were developed with *D* 19.

The density produced by the post-exposure alone varied from 0·007 to 0·11. For all post-exposures an increase of density of 50–100 per cent over that without post-exposure was obtained. Pre-exposure gave no appreciable effect. This agrees with the general rule that intensification can only be obtained if a long low-intensity exposure follows a short high-intensity exposure. The exposure of a grain hit by a β-ray is, of course, very intense and short in time.

Fuller details of this work will be published in due course in the *Revue de la Faculté des Sciences de l'Université d'Istanbul*.

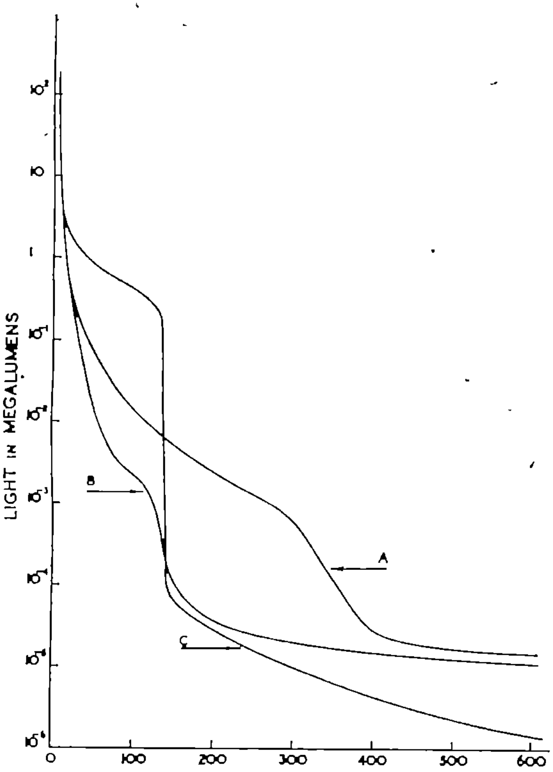
Decay of Light to Very Low Levels from Spark Discharges

RECENT publications on the after-effects from the electrical explosion of wires[1] and in Geiger counters[2], the cold emission of electrons in spark gaps[3] and the light output of sparks[4] suggest that the following experiments may be of interest, as we have not seen comparable results reported elsewhere.

We have observed the decay of light from pulsed high-current discharges in several gases and liquids down to extremely low levels and extending for several hundred microseconds. Single, approximately rectangular, current pulses obtained from a condenser network charged to 10 kV., of 1–9 μsec. duration and 100–10,000 amp. peak value, were used with electrode separation of a few millimetres. Triggering was effected by means of a trigger pulse applied to an auxiliary electrode. The light output was detected by means of an *RCA* 931*A* photomultiplier cell, amplifier and oscillograph. By altering the high



Decay of light from pulse discharges, 6,000 amp. peak and 6 μsec. duration: (*A*) in air, (*B*) in a rapid air stream, and (*C*) in water at 60 atm. pressure

tension of the cell and by the use of optical filters, the range of light output that could be measured was greater than 10^8 to 1, and the recovery time of the system from saturation due to the peak light was only about 20 μsec.

The types of decay curves obtained under various conditions are shown in the accompanying graph. Curve *A* is for a 6,000-amp. discharge between steel electrodes in air. The light decays very rapidly to about 10^{-4} of peak in the first 100 μsec. The rate of decay afterwards is much slower until a level of about 10^{-7} of peak is reached at 400 μsec., and this level is then maintained nearly constant to at least 600 μsec. This persistence of light at a low level is not due, apparently, to excited atoms remaining in the gap, as when the gap is swept by a powerful air blast only the initial rate of decay is changed, as shown in curve *B*. A similar curve is also obtained when possible direct radiation from the electrodes is screened off from the cell.

It was also found that the shape of the light decay curve is not significantly affected by the value of the peak current over the range investigated, but a slightly slower decay-rate is obtained when the pulse length is increased from 2 to 9 μsec. Slower initial decay-rates are obtained when the more volatile metals, such as aluminium, are used for the electrodes. Results similar to the air spark are obtained from discharges in photographic flash tubes, designed for a flash of a few microseconds duration, and in trigatrons.

Similar effects have also been observed with discharges in water; but in this case the initial rate of decay showed a marked increase when the water was subjected to considerable pressure, presumably due to the quicker collapse of the vapour bubble formed by the discharge. This effect is shown by curve *C* for a pressure of 60 atmospheres.

In all cases tried, light is still being emitted at a level of 10^{-7}–10^{-8} of peak some 600 μsec. after the current pulse, and this is not materially influenced by the conditions of the discharge. It is possible that ionization produced by continued electron emission from the cathode may account for this effect, and further study may yield new information on the processes involved. It is hoped to publish more detailed results in due course.

This communication is published by permission of the Chief Scientist, Ministry of Supply.

Rotational Analysis of the Columbium Oxide Bands

The bands of columbium oxide have been photographed on a 21-ft. concave grating with 30,000 lines per inch. The rotational analysis of three of these bands, λ 4,510 (1,0), λ 4,689 (0,0) and λ 4,915 (0,1) has been carried out. The rotational structure is found to resemble very closely that of vanadium oxide. Two *R* and two *P* branches have been identified in each band. The following constants have been determined for the ground and excited states:

$B_e' = 0{\cdot}5396$ cm.$^{-1}$ $B_e'' = 0{\cdot}6557$ cm.$^{-1}$
$B_0' = 0{\cdot}5325$ cm.$^{-1}$ $B_0'' = 0{\cdot}6553$ cm.$^{-1}$
$B_1' = 0{\cdot}5185$ cm.$^{-1}$ $B_1'' = 0{\cdot}6545$ cm.$^{-1}$
$\alpha' = 0{\cdot}0140$ cm.$^{-1}$ $\alpha'' = 0{\cdot}0008$ cm.$^{-1}$
$I_e' = 50{\cdot}32 \times 10^{-40}$ gm.cm.^{2} $I_e'' = 42{\cdot}18 \times 10^{-40}$ gm.cm.^{2}
$r_e' = 2{\cdot}237 \times 10^{-8}$ cm. $r_e'' = 1{\cdot}874 \times 10^{-8}$ cm.

The *D* values for the two states are of the order of 10^{-6} cm.$^{-1}$. Details of this work will be published elsewhere.

Eye Rotations with Change of Accommodation

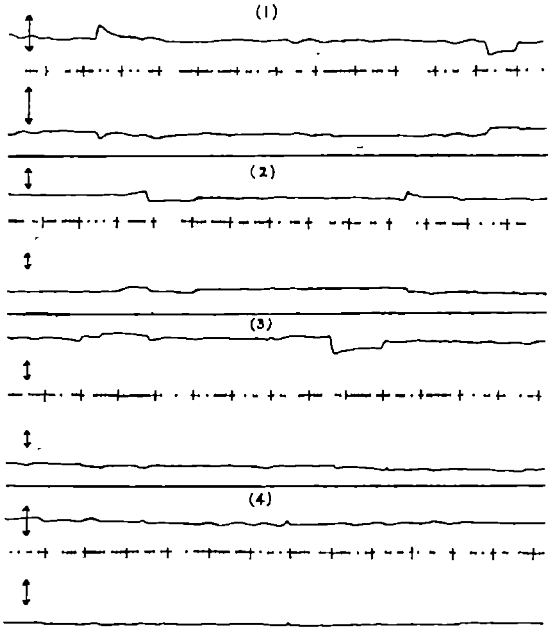
The apparatus, previously described[1], for studying eye movements of subjects in the sitting position, has been expanded so that side-to-side and up-and-down movements of the right eye can be recorded simultaneously. Rotations of this eye, occurring when accommodation is changed, have been studied with the apparatus. In these experiments, two fixation targets were used; both lay on the visual axis of the right eye when this eye was looking straight ahead. The farther target, which was viewed through a glass plate, was a bright pin-hole, angular diameter 1′, distant 5½ ft. from the subject. The nearer target was the mid-point between two virtual images, formed by reflexion at the front and rear surfaces of the glass plate, of another bright pin-hole. The virtual images were 2 ft. from the subject and the separation between them was 23′. Records were obtained for both horizontal and vertical separations of the virtual images. The subject fixated the far and near targets alternately; this cycle was repeated several times during a single recording, the frequency being at the subject's discretion. Records were obtained for both binocular and right-eye viewing of the targets.

As in the case of subjective change of convergence[3], change of accommodation was found to be associated with head movements similar to those occurring during steady fixation. Records for subjects R. S. L. and J. P. T. are independent of the direction of separation of the virtual images. It appears that change of accommodation is associated with a saccadic excursion of the eye, followed by return to its original fixation direction; saccadic movements are superimposed on the return drift in 50 per cent of the changes for J. P. T. and in 35 per cent for R. S. L. Characteristic records for R. S. L. for binocular viewing, and for J. P. T. for monocular viewing, are shown in Figs. 1 and 2 respectively. The average interval between changes is 1·7 sec. for R. S. L. and 1·6 sec. for J. P. T. For both subjects, the movements are oblique; for binocular viewing, the average magnitudes of the components for R. S. L. are 1·1° side to side, and 0·4° up and down; for J. P. T., they are 1·9° side to side, and 1° up and down. The monocular averages for R. S. L. are 0·8° side to side, and 0·3° up and down; for J. P. T., they are 1° side to side, and 0·7° up and down. For J. P. T., increase of accommodation is associated with a nasalward saccadic movement, and relaxation with a templeward saccadic movement. For R. S. L., the converse occurs for binocular viewing; for monocular viewing, nasalward saccadic movements are associated sometimes with increase, and sometimes with relaxation, of accommodation. The number of nasalward-upwards, nasalward-downwards, templeward-upwards and templeward-downwards saccadic rotations are approximately equal for J. P. T. For R. S. L., on the other hand, nasalward-upwards and templeward-downwards movements each comprise about 40 per cent of the saccadic rotations.

Injury to subject F. H. interrupted the investigation of his accommodation eye movements. However, the records obtained, which are for horizontal separations only of the virtual images, indicate qualitatively similar behaviour to that found for the other subjects. A characteristic record for F. H. is shown in Fig. 3.

Since the records are similar for the two directions of separation of the virtual images, it seems unlikely that there are any eye movements due to uncertainty of the subject about the position of the near fixation target. Moreover, steady fixation eye records[2] for such a target are similar to those for a single bright point.

For binocular viewing, Hering's[4] law predicts that, for the target configuration of this investigation, increase of accommodation would be accompanied by a nasalwards movement through about 2°, compounded with a templewards movement of equal magnitude. The behaviour of none of the subjects is in accord with this theory; in every case, the saccadic movements are oblique. Moreover, for subject R. S. L., the magnitude of the sideways component is smaller than that required by the theory. As for subjective change of convergence[3], the observed movements may be explained in terms of the energization, in activity, of the extra-ocular muscles.



(1) Right-eye record for binocular viewing for R. S. L.; separation of virtual images vertical.
(2) Right-eye record for right-eye viewing for J. P. T.; separation of virtual images horizontal.
(3) Right-eye record for binocular viewing for F. H., separation of virtual images horizontal.
(4) Right-eye record for right-eye viewing for A. L.; separation of virtual images vertical.
In Figs. 1–3, the movement at the extreme left of the record corresponds to increase of accommodation.
Side-to-side records are above the time-line; towards the time-line corresponds to nasalwards.
Up-and-down records are below the time-line; towards the time-line corresponds to upwards.
Time (increasing to right) | . . . | represents 0·2 sec.
Height of arrowed line represents a rotation of 3°, assuming the separation of the centre of curvature of the cornea and the centre of rotation of the eye is 5·3 mm.

Since most visual experience is binocular, an eye is accustomed to rotate when a change of its accommodation only is required. It is therefore not surprising that right-eye movements, on changing accommodation, should persist even when the left eye is screened; the movements are, however, somewhat smaller than those for binocular viewing, and, for R. S. L., are not always in the same direction.

To investigate whether eye rotations on changing accommodation arise entirely from binocular visual experience, records have been obtained for a subject whose visual experience is effectively monocular. The right eye of this subject, A. L., is emmetropic, acuity 6/4; with a correction of 1·5 D sph. combined with a $-$ 2·5 D cyl. (axis 15°), the left eye acuity is 6/18. A. L. has never worn glasses, and normally the left-eye vision is suppressed. His records are independent of the direction of separation of the virtual images, but otherwise differ considerably from those previously described; a characteristic record is shown in Fig. 4. The records for monocular and binocular viewing are similar and are little different from steady fixation records. It thus seems likely that binocular visual experience is entirely responsible for eye movements associated with change of accommodation, and that the precise nature of the movements depends on the energization, in activity, of the extra-ocular muscles.

I am grateful to Dr. R. S. Longhurst for acting as subject and for interesting discussions; and also to my students, Messrs. F. Hodgson, A. Langridge and

J. P. Tilt, who took part in the investigation. Mr. E. F. Fincham kindly helped in connexion with the refraction test. The continued financial support of the Medical Research Council is gratefully acknowledged.

Education of the Deaf

MAY I be allowed to make a material correction to the otherwise admirable account in *Nature* of September 27, p. 525, of the discussion on the "Education of the Deaf" at the recent meeting of the British Association ? My own paper was specifically limited to the problem of educating the young, totally deaf—whether born deaf, or those who become totally deaf before learning to speak.

It is common ground that such children constitute a very difficult problem. Mr. Greenaway reported that of twenty deaf pupils leaving his school this year, 60 per cent could be considered as successes, but the remaining 40 per cent were unsuccessful. For these he suggested that something more than pure oral teaching should be added.

Mr. Askew, of the Mary Hare Grammar School, pointed out that the born-deaf pupils entering his school at 13 + years were 2–3 years retarded in vocabulary. Prof. and Mrs. Ewing claim that with skilful home training from a very early age, deaf children of two had been trained to lip-read. But they have also admitted that all totally deaf children are not equally teachable.

My purpose was to plead for the experimental use of a systematic sign language, in which every sign should be the equivalent of a spoken word, and that suitable parents or nurses should be trained to use the new signs, and to talk to the young deaf children, *in signs*, just as a hearing mother talks to her young hearing children in words. In this experiment *no effort should be required on either side*. At first the deaf child would understand nothing : then gradually the meaning of the various signs would begin to dawn on them.

Mr. Greenaway had made the interesting suggestion that parents or nurses using the new sign language should speak as they signed. In this way the deaf children would get to realize that the mouth-gestures of speech and the pantomimic hand-gestures of the new sign language *meant* the same things. It seems not unlikely that at the age of four, totally deaf children might acquire a vocabulary of as many signs as a hearing child of equal intelligence would know words. A born deaf child of four with a vocabulary approaching 2,000 'words' would obviously be immensely more teachable than even the best of the pure oral successes. It is also obvious that signs which are completely visible should be much easier for the deaf child to imitate than spoken words are to the hearing child ; for the method of manufacture of speech-sounds is largely a secret process.

I have made no 'recommendations'—I plead for the carrying out of an experiment which seems to offer valuable knowledge and material help to the young born deaf. I plead in good company, for when Lady Paget and I met Dr. Helen Keller in Cape Town last year, she was greatly interested in the new signs, and, after copying some of them for herself, she gave me this message : "Let the experiment be tried".

In vitro Cultures of a Fern Callus

IN recent years, several reports of the successful growth in sterile culture of callus tissues derived from various pteridophytes have appeared[1]. A callus culture possessing several unusual morphological, cytological and metabolic features has been obtained from gametophytes of *Pteridium aquilinum* (L.) Kuhn, var. *latiusculum* (Desv.) Underw.[2], which had been growing in sterile culture on an agar medium containing Knudson's solution of inorganic salts[3], Berthelot's trace element solution[4], 2 per cent glucose and 0·5 gm./l. yeast extract (autoclaved) at Harvard University, United States. Soon after these gametophyte cultures were brought to Manchester, England (in September 1950), a callus-like growth was observed in one of the tubes. When subcultured on to the same medium, with Knop's inorganic salt solution[4] substituted for Knudson's, the abnormal tissue continued to grow in a disorganized manner. It has now been through sixteen passages, each of four to six weeks duration, and in each passage there has been a six- to ten-fold increase in the size of the inoculum.

The cultures are deep green in colour and form coherent but friable masses. They are predominantly filamentous, with numerous branched filaments radiating from centres of growth. Continued divisions in various planes result in the formation of regions of highly vacuolated, large-celled parenchymatous tissue in some of the older parts of the cultures. Whitish or pale-green outgrowths project from the surfaces of many of the cultures. These are compact tissues composed of small, deeply staining parenchyma cells. Meristematic growth in the outgrowths is confined to certain localized superficial regions behind which is often a core of elongated cells. Some of these cells may be further differentiated as short scalariform or reticulate tracheids. A variety of treatments has as yet failed to promote further regenerative growth of these bud-like structures.

During the first two passages prothallial regeneration occurred on five occasions, but has not occurred since, either spontaneously or following experimental treatment. The strain of gametophytes from which the callus arose was haploid[2]; $n = 52$. When first examined in the fourth passage, cells of the callus had approximately 100 chromosomes ; but on subsequent examination of material in the twelfth and fourteenth passages chromosome numbers were found to vary irregularly between 150 and 200. The callus is now irregularly aneuploid.

Nutritional requirements of the callus are very simple. Slow but continued growth is possible on an agar medium containing inorganic salts only. Rapid growth occurs when inocula are totally submerged in a liquid medium containing only inorganic salts and 3 per cent glucose.

A detailed account of these cultures will be published elsewhere.

Our thanks are due to the late Mr. A. Swaffer and to Dr. C. M. Wilson and Mr. C. Partenan for assistance with the cytological studies.

A Difference in *In vitro* Pancreatic Digestion between Animal and Plant Protein Feeds

MELNICK *et al.*[1] and Evans[2] found that the rate of enzymatic liberation of amino-acids from soybean proteins preheated at different temperatures provides an explanation for their different growth-promoting properties for the growing chick. We have used this principle to investigate the differences between the biological value of various types of protein feeding-stuffs for animals. In the course of this work we observed a property in which plant and animal proteins differ: pancreatic digests of plant protein feeds, but not of animal protein feeds, yielded considerable precipitates on addition of trichloracetic acid.

The experiments were carried out with feeding-stuffs defatted with ether and dried at room temperature. 6-gm. samples of each feed were placed in 250-ml. Erlenmeyer flasks, 300 mgm. of 'Pancreatin' (Byla, Paris), 150 ml. of phosphate buffer (*p*H = 8·2; Sørensen) and a few drops of toluene were added. The flasks and contents were incubated at 37–38° C. for 48 hr. with frequent shaking. In one set of experiments the non-digested materials were filtered, washed several times with phosphate buffer (*p*H = 8·2) and the nitrogen content of the precipitates was determined by Kjeldahl digestion. In a second set the whole digests (together with the substrates) were acidified with hydrochloric acid (methyl red) and 25 ml. of 5 per cent trichloracetic acid added. The precipitates were filtered and washed with hot water containing 0·5 per cent trichloracetic acid.

The precipitates obtained by addition of trichloracetic acid to plant protein digests contained much larger amounts of nitrogen than the non-digested residues by themselves, amounting to 20–25 per cent of the nitrogen contained in the original feeding-stuff. In the case of the pancreatic digests of animal-protein feeds, addition of trichloracetic acid did not cause precipitation of any additional quantity of nitrogen.

Feed	Total N-content of the fat-free feed (per cent)	Insoluble N after 48 hr. digestion with 'Pancreatin'	Insoluble and precipitated N after addition of $CCl_3.COOH$ to pancreatic digests
		In per cent of the N-content of the fat-free feed	
1. Fish meal (Norwegian)	11·6	40·1	40·1
2. Meat-meal (Argentinian)	11·4	25·0	25·8
3. Soy bean oil meal	7·7	10·3	30·0
4. Sesame oil meal	7·9	16·6	42·5

It may be noted that in similar digestion experiments carried out with pepsin (*p*H 1·5), no additional nitrogen was precipitated by trichloracetic acid, either in digests of plant proteins or in those of animal proteins.

Experiments to elucidate the chemical nature of these soluble nitrogen compounds precipitated by trichloracetic acid are under way.

Production of Gliotoxin in Unsterilized Soil

IT has long been recognized that microbial antagonisms exist in the soil, and the possibility that this might be due to production of antibiotics has been suggested although never actually proved.

It has been shown that soil can be used as a medium for growth of many micro-organisms and also for antibiotic production, but in general sterilizing and supplementing with organic matter have been found to be necessary. Grossbard[1] has demonstrated the production of an antibiotic in autoclaved and also in partially sterilized soil, and Hessayon[2] has shown that activity can be produced in sterile unsupplemented soil. Gregory, Allen, Riker and Peterson[3,4], moreover, have demonstrated activity in unsterile soil which was, however, supplemented with highly nutrient organic matter. In these cases it was assumed, but not conclusively demonstrated, that the antibiotic formed in the soil was identical with that produced by the fungus in synthetic media.

The results presented here show the production of gliotoxin by *Trichoderma viride* in Wareham Heath soil, a highly acid podsol, in which all the microflora was present.

Unsterile soil was supplemented with dried clover, inoculated with a spore suspension of a gliotoxin-producing strain of *T. viride* and incubated at 25° C. for four days. The soil was extracted with ether and the extract used to demonstrate and identify the antibiotic.

Identification was demonstrated by a bio-assay based on paper chromatography. Chromatograms were run on the soil extracts, and solutions of pure gliotoxin on filter paper strips, and these were placed on agar seeded with *B. subtilis* as the test organism. After incubation of plates the distance moved by the active substance was demonstrated by the position of a clear zone of inhibition and the R_F values were calculated. The amount of gliotoxin present could be estimated roughly from the size of the inhibition zone.

	R_F values
Pure gliotoxin	0·60
Inoculated soil + 5 per cent clover	0·59
Inoculated soil + 2 per cent clover	0·59

Activity was produced only in inoculated unsterile soil to which dried clover had been added, and as the R_F values of these extracts and pure gliotoxin were very similar, it was assumed that the activity was due to production of gliotoxin by the fungus. It was estimated, very approximately, that 0·6 μgm. of gliotoxin/gm. of soil was produced when 5 per cent dried clover was added. Activity was produced in soil to which only 1 per cent dried clover had been added.

A neutral garden loam was treated in the same way and inoculated with *T. viride*; but activity could only be demonstrated in soil which had been acidified. It has been shown by Jefferys[5] that inactivation of gliotoxin is more rapid in garden soil than in Wareham soil, and he related this to difference in *p*H, as gliotoxin is more stable at lower *p*H values.

Relationship of the Blood Sub-Groups A_1, A_2 and A_1B, A_2B to Hæmagglutinins Present in the Seeds of *Dolichos biflorus*

To identify the blood sub-groups of A and AB, an anti-A_1 serum is used. This is prepared by completely absorbing a human anti-A serum with A_2 cells[1]. The absorbed serum agglutinates A_1 and A_1B cells, but not A_2 or A_2B cells. A-specific hæmagglutinins have been demonstrated in saline extracts of the seeds of *Dolichos biflorus* by Bird[2], and it has been suggested[3] that because extracts of *Dolichos biflorus* seemed predominantly A_1-specific, they may be used to differentiate the sub-groups A_1 and A_2, A_1B and A_2B. The seed extracts have the advantage of being cheaper and more easy to prepare than human sera.

Two hundred samples of A and seventy-five of AB cells were therefore tested both with a human anti-A_1 serum and a saline extract of *Dolichos biflorus* seeds. All the samples were of Indians of no definite ethnological status and were obtained from the local blood-donor centre; 2 per cent suspensions of washed cells in isotonic saline were used. All the samples were less than 24 hr. old. The seeds used were those of *Dolichos biflorus*—Belgaum 1-1-8. They were extracted with isotonic saline by the simple method used by Boyd and Reguera[4] for small quantities of seeds. To differentiate A_1 from A_2 the seed extract was titrated against all the A samples. There was a clear-cut differentiation of the sub-groups of A, A_1 cells being agglutinated in titres ranging from 8,192 to 32,768; and A_2 cells in titres ranging from 4 to 16. In the case of AB cells, no titration was required as the undiluted extract agglutinates A_1B cells strongly and almost immediately, while it agglutinates A_2B cells weakly after about 15 min.

There was complete correspondence between the results obtained with the seed extract and those obtained with the absorbed human serum. There was no sample of A or AB which could not definitely be assigned to its proper sub-group; that is, there was no evidence of the occurrence of any 'A intermediates'. For routine work, a 1 in 64 dilution of the fresh extract in isotonic saline could be conveniently used to differentiate A_1 from A_2. This dilution can also be used to distinguish A_1B from A_2B, because A_1B cells are acted upon[3] up to a titre of 512.

Of the A samples, 177 (88·5 per cent) belonged to the sub-group A_1 and 23 (11·5 per cent) to A_2; while of the AB's, 60 (80 per cent) were A_1B and 15 (20 per cent) A_2B. As the numbers tested are small, and as the group examined was ethnologically indefinite, the anthropological aspect of these figures is not discussed.

Copepods New to British Waters

DURING a recent investigation on ascidicolous copepods, at least five species hitherto unrecorded from British waters have been found in Strangford Lough, Co. Down. All are members of the sub-order Notodelphyoida, and are listed below, together with their host ascidians.

Doropygus uncinatus Kerschner. in *Polyclinum aurantium* Milne Edwards and *Sidnyum turbinatum* (Savigny).
Enterocola pterophora Chatton and Brément: in an unidentified didemnid.
Haplostomides scotti Chatton and Harant: in *Polyclinum aurantium*.
Haplostoma brevicauda (Canu). in *Polyclinum aurantium*, *Sidnyum turbinatum* and *S. elegans* (Giard).
Haplostoma banyulensis (Brément). in *Trididemnum tenerum* (Verrill).

Five other notodelphyoids so far known only from isolated localities around the British Isles and recorded, for the most part, many years ago, have also been discovered in Strangford Lough, and are given in the subjoined list.

Gunenotophorus globularis Costa in *Pyura squamulosa* (Alder) and *Polycarpa* sp.
Botryllophilus ruber Hesse: in *Botryllus schlosseri* (Pallas) and *Botrylloides leachi* (Savigny).
Enterocola fulgens P. J. van Beneden: in *Polyclinum aurantium*.
Haplostomides hibernicus (T. and A. Scott) in *Polyclinum aurantium*.
Mycophilus roseus Hesse: in *Botryllus schlosseri* and *Botrylloides leachi*.

I have hesitated for some time to assign specific identity to the *Mycophilus* collected, due to the presence of two forms in the lough. One of these is undoubtedly similar to that described by Chatton and Brément[1] as *Mycophilus curvatus*, while the other is apparently identical with *M. vararensis*, originally described by T. Scott[2] as *Enteropsis vararensis* but later annexed to the genus *Mycophilus* by Chatton and Brément. There seems to be little doubt that a third form described by Gray[3] as *M. roseovula* is synonymous with Scott's species. Lang[4], however, regards all members of this genus as referable to the single species *M. roseus*. My own work supports Lang's conclusion; it is hoped to discuss this question more fully in a separate paper.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 20

Society of Dairy Technology (in the North Hall, Victoria Halls, Bloomsbury Square, London, W.C.1), at 2.30 p.m.—Dr. John Hammond, F.R.S.: "The Contributions of Artificial Insemination and Milk Recording to the Dairy Industry".

British Society for the History of Science (in the Lecture Room, Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Dr. Derek J. Price: "Chaucer's 'Equatorie of the Planetis'".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Institution and Current Affairs" (to be opened by the President).

Society of Chemical Industry, Crop Protection Panel of the Agriculture Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. J. M. Barnes: "Crop Protection as a Health Hazard".

Society of Chemical Industry, Corrosion Group (joint meeting with the Institute of Metal Finishing, at the Northampton Polytechnic, St. John Street, London, E.C.1), at 6 p.m.—Mr. H. M. Angles, Mr. S. C. Britton and Mr. D. G. Michael: "Tin-Nickel Alloy Coatings".

Tuesday, October 21

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. J. B. S. Haldane, F.R.S.: "Indian Culture, Past and Present".*

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mrs. Margaret Pyke and Mr. H. A. Davidson: "Family Planning—the Past and the Future".*

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. L. Hartshorn: Chairman's Address.

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. P. S. Williams: "The Flow of Concentrated Suspensions (related to Chemical Engineering Problems)".

Textile Institute, London Section (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Mr. F. Courtney Harwood: "Modern Detergency".

Wednesday, October 22

Aslib (at Friends House, Euston Road, London, N.W.1), at 5.30 p.m.—Mr. J. E. L. Farradane: "Psychology of Classification".

British Psychological Society, Medical Section (at the Medical iety of London, 11 Chandos Street, Cavendish Square, London, 1), at 8.30 p.m.—Dr. N. Tinbergen: "Some Recent Work on tinct".

Thursday, October 23

nstitution of Electrical Engineers, Utilization Section (at oy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.— J. W. T. Walsh: Chairman's Address.

Friday, October 24

Biochemical Society (in the Department of Biochemistry, St. omas's Hospital Medical School, London, S.E.1), at 2 p.m.—ntific Papers.

hemical Society, Glasgow Section (joint meeting with the hemist's Club and the Andersonian Chemical Society, at the yal Technical College, Glasgow), at 3.30 p.m.—Prof. D. H. Hey: ubstitution at an Aromatic Carbon Atom".

hemical Society, Birmingham Section (joint meeting with the University Chemical Society, in the Chemistry Lecture Theatre, The University, Edgbaston, Birmingham), at 4.30 p.m.—Dr. V. C. Barry: "Studies in the Chemotherapy of Tuberculosis".

British Glaciological Society (in the Department of Geography, Downing Place, Cambridge), at 8.15 p.m.—Prof. R. Finsterwalder: "Glacial Recession in the Eastern Alps since 1850, with special reference to Recent Times". (Members of the University are invited.)

Friday, October 24—Saturday, October 25

Institute of Physics, X-Ray Analysis Group (at the Royal Institution, 21 Albemarle Street, London, W.1).—Autumn Conference.

Saturday, October 25

British Glaciological Society (joint meeting with the Scott Polar Research Institute, at the Institute, Cambridge), at 8.30 p.m.—Dr. G. de Q. Robin: "The Norwegian–British–Swedish Antarctic Expedition, 1949–1952". (Members of the University are invited.)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Bacteriologist (science graduate, non-medical)—The Secretary and Administrative Medical Officer, Northern Regional Hospital Board, Raigmore, Inverness (October 25).

Engineers (with good research experience) at the new Research Establishment at Isleworth, Middx, to undertake research work on underground mining problems—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/540 (October 25).

Lecturer in the Mechanical Engineering Department of the Municipal Technical College—The Chief Education Officer, Guildhall, Kingston-upon-Hull (October 25).

Senior Experimental Officer at the Aeronautical Research Laboratory, Fishermen's Bend, Victoria, Australia, to be responsible under a P.S.O. (instrumentation) for the design, development, and manufacture of special instrumentation required for laboratories—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1, quoting No. 268 (October 25).

Senior Scientific Officers: (Position No. 3) to be responsible under direction of a P.S.O. for supervising a chemical section for research and investigations related to materials for rocket motors and rocket propellants; (Position No. 14) to be responsible under direction of a P.S.O. for supervising internal ballistics research in the field of rocket propulsion, including determination of ballistic properties of propellants and design of charges for rocket motors; Principal Scientific Officers: (Position No. 24) to be responsible for initiation of research on the theoretical aspects of rocket propulsion and to supervise mathematical, thermodynamic and heat transfer studies in this field; (Position No. 34) to be responsible for the organization and direction of a propulsion engineering group, to initiate and supervise research and development on the engineering aspects of rocket motor design and exercise general supervision over an experimental workshop, drawing office and static firing emplacements; at the Propulsion Research Laboratory, Salisbury, Australia—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1, quoting the appropriate Ref. No. (October 25).

Research Assistants (2, with a first- or second-class honours degree, preferably in chemistry or biochemistry) in a newly formed Unit of Insect Biochemistry, to undertake research upon the biochemistry of locust blood—The Registrar, The University, Leeds 2 (October 27).

Senior Physicist in the Department of Medical Physics—The Secretary to the Board, United Bristol Hospitals, Royal Infirmary Branch, Marlborough Street, Bristol 2 (October 27).

Museum Assistants in the Science Museum and the British Museum—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 143/229/52 (October 30).

Assistant Lecturer in the Department of Agriculture (Crop Husbandry)—The Registrar, University College of Wales, Aberystwyth (October 31).

Assistant Lecturer or Lecturer in the Department of Mining—The Registrar, University College, Cathays Park, Cardiff (October 31).

Demonstrator (honours graduate with previous experience of demonstrating to B.Sc. standard) in the Physics Department—The Registrar, King's College, Strand, London, W.C.2 (October 31).

Foulerton Research Fellowship in Medicine—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (October 31).

Junior Lecturer in Anatomy—The Registrar, King's College, Strand, London, W.C.2 (October 31).

Lecturer (Grade II) or an Assistant Lecturer (Grade III) in the Department of Physics—The Secretary, The University, Birmingham 3 (October 31).

Lecturer in Palæontology and Stratigraphy—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (October 31).

Lecturer or Assistant Lecturer in the Department of Geology—The Registrar, University College of Wales, Aberystwyth (October 31).

Lecturer in Metallurgy—The Registrar, King's College, Newcastle-upon-Tyne (October 31).

Scholarship for Training in Industrial Research—The Director, Institute for Industrial Research and Standards, Glasnevin House, Ballymun Road, Dublin (October 31).

Head of the Department of Biochemistry—The House Governor, Children's Hospital, Ladywood Road, Birmingham 16 (November 1).

Technical Officer, Grade II (with a good general training in chemistry, preferably up to degree standard; experience in fuel technology and fuel analysis would be an advantage) at the Coal Survey Laboratory in Scotland—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/539 (November 1).

Senior Principal Scientific Officer and Principal Scientific Officers at the Army Operational Research Group, West Byfleet, Surrey, and a Principal Scientific Officer or Senior Scientific Officer at the Ordnance Survey Office, Chessington, Surrey—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4165/52 (November 6).

Assistant Lecturer (temporary) in the Department of Anatomy—The Registrar, University College, Cathays Park, Cardiff (November 8).

Research Studentship in the Department of Biochemistry—The Secretary, Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S.W.1 (November 8).

Senior Research Officer (chemist or chemical engineer) at the Wool Textile Research Laboratory, Geelong, Victoria, Australia, to establish a section for research into certain processes of the textile industry, particularly felting and scouring—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3880 (November 8).

Brotherton Lecturer in Chemical Engineering—The Registrar, The University, Leeds 2 (November 10).

Rose Sidgwick Memorial Fellowship for a year's postgraduate study in the U.S.A., and the Aurelia Henry Reinhardt International Fellowship for a year's research in some country other than the holder's own—Research Applications, British Federation of University Women, Ltd., 17a King's Road, London, S.W.3 (November 15).

Director of Research at the Australian Leather Research Association at Lane Cove, near Sydney, New South Wales—The Australian Leather Research Association, c/o the Chief Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2 (November 22).

Lecturer in Philosophy at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Melbourne, December 1).

Postdoctorate Fellowships for research in pure chemistry and physics, tenable in the National Research Council's laboratories at Ottawa, and Postdoctorate Fellowships in the biological sciences, tenable in the Prairie Regional Laboratory of the National Research Council at the University of Saskatchewan and in the Laboratories at Ottawa—The Secretary, Laboratories Awards Committee, National Research Council, Ottawa, Canada; or the Chief Scientific Liaison Officer, National Research Council of Canada, Africa House, Kingsway, London, W.C.2 (February 15).

Assistant (Grade A) in Biology (qualified to take botany and/or zoology to Intermediate Degree standard), and an Assistant (Grade A) in Physics—The Principal, Technical College, Queen Street South, Huddersfield.

Assistant Technical Secretary (with a degree in metallurgy; some industrial experience essential, and a knowledge of sheet metal products an advantage) by the Metallurgy (General) Division—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Technical Secretary'.

Bacteriologist to undertake research work on the classification and identification of rumen bacteria by serological methods—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

Chair of Mathematics—The Secretary, Royal Technical College, George Street, Glasgow, C.1.

Chemist (with good honours degree and Ph.D., or equivalent research experience) for work involving isolation and purification of new antibiotics and other substances of biological interest—The Director, Antibiotics Research Station (Medical Research Council), 4 Elton Road, Clevedon, Somerset.

Civil Engineer in the Hydrological Survey Department, Uganda—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting C.S.D.64/9/01.

Demonstrator in Agricultural Zoology in the Department of Agricultural Sciences, School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

Demonstrator in Chemistry and Biology—The Registrar, Technical College, Sunderland.

Entomologist in the Department of Agriculture, Trinidad, for investigation of plant damage by insects and other animals and formulation and application of control measures; also plant quarantine work—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting C.S.O 63/38/01.

Geologist (with honours degree in geology) for service in the Antarctic with the Falkland Islands Dependencies Survey—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.33272.B.

Graduate Chemist for investigations of cleaning and lubrication in metal working processes (location, Sheffield)—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Lubrication'.

Hugh Wood Memorial Fellowship in Mining—The Registrar, The University, Leeds 2.

Industrial Chemist at Harwell, to assist in problems associated with treatment of radioactive material, water supplies, and general chemical service—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House 26 King Street, London, S.W.1, quoting F.046/52A.

Lecturer in Biology in the Department of Applied Science, Wolverhampton and Staffordshire Technical College—The Clerk to the Joint Education Committee, Education Offices, North Street, Wolverhampton, Staffs.

Lecturer in Mechanical Engineering, including heat engines and hydraulics—The Principal, Faraday House College, Southampton Row, London, W.C.1.

Lecturer in Organic Chemistry, to teach organic chemistry to the standard of the Special Degree in Chemistry of London University, and the A.R.I.C.—The Registrar, Municipal College, Portsmouth.

Lecturer or Assistant Lecturer in the Department of Aeronautical Engineering—The Secretary and Registrar, The University, Southampton.

Mycologist (with an honours degree in botany, with experience of research in mycology and economic botany) in the Forest Department, Kenya, to study pathology in forests and plantations and the fungal diseases of timber—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CSO.61/7/01.

Professor of Mechanical Engineering and a Professor of Electrical Engineering at the University of Roorkee, U.P., Northern India, to teach and organize their departments on modern lines with up-to-date undergraduate and postgraduate courses and research—The Ministry of Labour and National Service, Technical and Scientific Register (A.8.12), Almack House, 26 King Street, London, S.W.1, quoting A.12/1.65,66E/52.

Research Assistant (with a good honours degree in physics, mathematics or chemical engineering, and some research experience) in the Department of Mining and Fuels—The Registrar, The University, Nottingham.

Research Assistant (with a good degree in zoology and, preferably, a special interest in physiology and histology)—The Professor of Zoology, The University, Glasgow, W.2.

Research Demonstrator (honours graduate in botany) in the Department of Biology—The Registrar, University College, Singleton Park, Swansea.

Research Manager at Sellafield, Cumberland, to take charge of Laboratories engaged on metallurgical development of radioactive materials and welding processes for atomic energy—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting Ref. 376.

Research Physicist (with at least a second-class honours degree in physics) for work in the field of Solid State Physics—The Professor of Physics, The University, Reading.

Scientific Officer or Senior Scientific Officer for an investigation on the soundness of iron castings—The British Cast Iron Research Association, Alvechurch, Birmingham.

Senior Engineer, Water Supply and Irrigation Department, Cyprus—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting C.S.D.64/17/01.

Senior Physicist (with experience in medical physics) for Radiotherapy Service of the Southampton area—The Secretary, Southampton Group Hospital Management Committee, Bullar Street, Southampton.

Surveyors in Uganda, to carry out and supervise cadastral and topographical surveys—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting C.S.D.72/9/01.

DEVELOPMENT OF BACKWARD COUNTRIES

PROF. A. V. HILL'S presidential address to the British Association should dispel any facile optimism as to the ability of science and technology to increase the world's food supplies—or to develop world resources generally—sufficiently rapidly to overtake the demands of a rapidly increasing world population. Whatever view is taken of the possibility of controlling the expansion of population, there can be no doubt as to the urgency of expanding as rapidly as possible, and with regard to long-term at least as much as to short-term needs, the world's food supplies, and developing world resources with equal regard to such long-term requirements rather than immediate exigencies. So far as Britain is concerned, when all that is possible has been done to improve the efficiency of food production and to remove waste—whether due to the destruction of crops in the field, or in transport or storage—the largest hope for increased production lies in the more backward countries. Only as the standards of cultivation are raised in those areas and the fullest use is made of available knowledge can there be any hope of raising the standards of living in those countries, or of making any contribution to the needs of the rest of the world.

Two recent broadsheets by Political and Economic Planning dealing with technical assistance have thus appeared at a time when Prof. Hill's address has directed general attention to a most important topic. The first of these broadsheets (No. 346) deals with agencies and programmes ; the second (No. 347) with policy and method. Both, however, are in direct sequence of an earlier broadsheet (No. 340. "The World's Food." April 7, 1952), which itself continued a discussion initiated in "Prospect of a Decade" (No. 328) and "The Strategy of World Development" (No. 327). They reiterate warnings already given, and bring to the examination of these problems the same sense of urgency and realism as characterizes Prof. Hill's address.

Much of the broadsheet "The World's Food" was occupied by a discussion of three recent books on world population and food supply which have attracted considerable attention. The view is accepted that unless starvation and malnutrition are to become very much more serious even than they are now, food supplies in many parts of the world will require to be more than doubled in the next fifty years. The earlier estimate, in "Prospect of a Decade", that less than three per cent of the earth's acreage is more or less satisfactory for the support and shelter of mankind is now regarded as too pessimistic ; but in reviewing the possibilities of increasing the area of land devoted to food production or increasing the production from a given area of land, P E P emphasizes the strong temptation in the present situation to farm for the greatest immediate yields, at the risk of reducing the fertility of the soil and exposing it to erosion.

If the human race continues to multiply at the present rate, catastrophe will only be avoided if methods of cultivation are used which, far from destroying the fertility of the soil, maintain or even increase it. Nor will it be possible to countenance the continuance of laws and customs regulating inheritance which in some countries lead to a fragmentation of land holdings and the prevention of efficient methods of cultivation. It is true that a limited number of people from the over-crowded areas of the world could feed themselves better if they were allowed to migrate to much less intensively settled areas; but apart from this, more food for the poorer people of the world means, for all practical purposes, more production in the areas where they live.

Here we are led to the question of technical assistance. Such increased production depends at first on the technically advanced countries providing the cost of such assistance and equipment. They must also assist by teaching improved methods of cultivation. Moreover, there is the question whether, even by such improved methods, sufficient food can be grown for all the peoples of the world without decreasing the land available for crops which are wanted by advanced countries as a source of raw materials for their industries. As population increases, it may become increasingly difficult for the richer countries to maintain or improve their standards of living without depressing people in other parts of the world below the subsistence level.

It is, of course, possible that the amount of cultivable land or the yields which can be obtained without exhausting fertility will prove to be considerably greater than can be safely predicted. Even if, however, the rate of growth in the world's population decreased sharply and sooner rather than later, or the use of novel sources of food gave greatly increased supplies, it is improbable that a clash of interests between the richer and the more backward parts of the world will be entirely avoided. Plans for technical assistance must, as P E P wisely insists, take full account of such possible conflict if they are to be realistic and effective, and must aim at reducing the clash or tension as much as possible.

The importance of this factor is well brought out in the two broadsheets on technical assistance. The first recognizes that some such areas may be able to develop their economy from their own resources, provided they can secure the highly trained men from outside to teach the new techniques and secure their adoption, and emphasizes the multiplicity of agencies at present available to supply such assistance. Even so, the importance of confidence is not obscured. Unless the government of the backward area can be trusted to honour its undertakings, the schemes break down, and men of integrity and ability are unlikely to be forthcoming.

Technical assistance provided through the specialized agencies set up under the United Nations, which is co-ordinated through the Technical Assistance Board, is provided only to, and at the request of, the government concerned, though many of the governments needing technical assistance require also to be helped to formulate reasonable requests. Such technical assistance is not to be used as a means of economic or political interference, and it is also laid down that the experts provided should possess some understanding of the needs, aims and social and cultural background of the country they are sent to assist. Normally, also, governments requesting assistance are expected to assume responsibility for a substantial part of the cost of the technical assistance provided.

Under such international agencies, 797 experts were recruited for under-developed countries by the end of 1951; of these, 271 were provided through the Food and Agriculture Organization, 155 through the World Health Organization, 109 through the United Nations Educational, Scientific and Cultural Organization, 65 through the International Labour Organization and 32 through the International Civil Aviation Organization. There are no figures to indicate the distribution of experts by activities or areas; but besides the technical assistance afforded in this way there is also that provided through the bilateral programmes of individual advanced countries, such as the United States Point Four programme and the British schemes promoted by the Colonial Office. Thirdly, there are the regional agencies and programmes exemplified by the Colombo Plan Council for Technical Co-operation, the Pan-American Union and the Inter-American specialized agencies, and the regional economic commissions for Asia and the Far East, and Latin America, set up by the Economic and Social Council of the United Nations, though the latter regional commissions have much broader functions as well.

By January 1952, under the Point Four programme, general agreements had been made with more than thirty governments, and some 619 United States technical experts were in the field; this figure ha[illegible] risen to 972 in thirty-three countries by June 30, 1952 Further, at the end of 1951, some 372 persons fro[illegible] other countries were receiving training in the Unite[illegible] States under the Technical Co-operation Administration. Besides the 35 million dollars appropria[illegible] for the Point Four technical assistance programm[illegible] the year ending June 30, 1951, the United States [illegible] contributes to technical assistance through such ot[illegible] means as the Fulbright Training Scheme, the Rockefeller Foundation and the Near East Foundation.

No comprehensive account of British technical assistance in the Colonies is available, and although the P E P broadsheet estimates expenditure on thi[illegible] as approaching £8 millions for the year endin[illegible] March 31, 1952, no estimate is given of the demand made for staff. No such estimate was attempted, it may be recalled, in the House of Lords debate on this question last May, when Lord Milverton quoted a figure of 150,000 for the annual output of trained men in the Commonwealth centres of South and South-East Asia. Under the Colombo Plan, however, only 45 out of 177 experts requested were secured in 1951, and only 309 trainees were placed out of 781 proposed. The Plan set a maximum of £8 millions, for technical assistance to be given in the three years from July 1, 1950; but by the end of 1951 expenses and commitments totalled no more than £400,000, and in general the Colombo Plan Council has concentrated on the supply of those types of technical assistance which are not available from other sources.

The first of these broadsheets thus illustrates the need for co-ordination between the numerous agencies concerned with technical assistance—a need which is fully recognized. Of requests for 242 experts made under the Colombo Plan up to the end of 1951, 65 were withdrawn, and out of 833 requests for places for trainees, 52 were withdrawn, mostly because the requests had been met through other channels. The fourth report of the Technical Assistance Board stressed the need for avoiding duplication of effort and competition between the programmes which recruit experts and use training facilities in the same countries. "Wide divergencies in the salary scales and allowances of experts or stipends of fellows, and notable differences in the contributions expected from under-developed countries to the local costs of projects under the different programmes can," the report observes, "seriously embarrass and slow down operations."

The Technical Assistance Board is endeavouring to mitigate the effects of any such competition by arranging exchange of information on administrative practices between the various bodies concerned; but there is general agreement that the main task of co-ordination must be undertaken in the under-developed countries themselves. Here, especially, the giving of technical assistance is bound to be a matter of considerable delicacy. In some under-developed countries, P E P frankly points out, economic progress may be impossible while the existing methods (or lack of methods) of government and tax collection remain. Such countries may be said to need technical assistance in reforming their government organization; but they may not welcome it, and meanwhile their imperfect standards hinder alike the co-ordination of technical assistance and the recruitment of experts. The latter, as the first annual report on the Colombo Plan emphasized, is by far the most difficult part of any scheme for technical co-operation.

To secure the services of the right kind of men is probably the most important single factor in the success of technical assistance. To this factor this second P E P broadsheet gives the attention it deserves, though the analysis is qualitative rather than quantitative. P E P does not consider the relation between what it terms the present 'infantile' demands of the technical assistance programmes for personnel and the shortage of scientific and technical man-power already existing in the United States and in Great Britain, for example. A present total of 2,500 or more experts is by no means a negligible drain on man-power resources, even if it were not expected to grow considerably.

If, as is rightly emphasized, the under-developed countries are insistent on demanding able men of established reputation and, at the same time, it is desirable that the experts supplied should be not only technically competent, but also able to apply their knowledge in the circumstances of an under-developed country or train people of very different backgrounds, it must be remembered that for such men there may be a great demand. Remunerative posts are likely to be available in their own countries, and it is not easy at best to induce them to transfer to the comparative discomfort of the backward areas. Some sense of vocation or call to disinterested service may be an essential motive, and undoubtedly would be the ideal. Integrity and tact, in fact, are as important as skill and ingenuity, for if technical assistance is to achieve its purposes, a new attitude of partnership must be fostered.

Political and Economic Planning has done well in this broadsheet to stress the critical importance of the technical expert and the need for careful training as well as selection, and it is welcome news that the Technical Assistance Board of the United Nations is studying methods of briefing experts both on the technical aspects of their assignments and on the social and economic conditions of the countries to which they are to be sent. The Institute of Social Studies, established by the Netherlands Universities through the Foundation for International Co-operation, also gives training and conducts research in matters relevant to technical assistance.

There are other factors which bear on this question of obtaining the right type of technical expert. The good conditions of service which it is essential to offer are related to the policy of requiring technical assistance to meet certain local costs. While this is sound from the point of view of stimulating interest and responsibility on the part of the receiving countries, such a policy can cause real hardship. One possible suggestion mooted in the P E P broadsheet is to institute some sort of deferred salary scheme. This might mitigate some of the disparity in standards of living, but admittedly it might fail to attract the very men whose assistance is most desired.

Insufficient experience is yet available for a sound judgment on such points as these. Other thorny problems are provided by the supply of equipment and of capital for development, while even more difficult are those that arise in regard to priorities and the balance of programmes. Officially the aim is still to provide assistance to all countries which request it, while allowing each country the final decision on the purposes for which it requires assistance. Nevertheless, as requests for technical assistance outrun the resources at the disposal of the various agencies, the danger may grow that technical assistance will be spread too wide and thinly to do any real good anywhere.

These and other questions are faced realistically in these broadsheets, which make no attempt to disguise the dangers which may attend the attempt to distribute assistance wisely and altruistically rather than in response to pressure of any kind. On the whole, the survey leaves room for hope. Instances are cited to illustrate the far-reaching effects of quite small projects launched with imagination and conducted with sympathy by the right type of expert. The emphasis on quality in technical assistance is already justified by experience as well as by theory; but if the right schemes are to be selected and launched at the right level, if they are to be staffed by men and women of the calibre desired, and carried through to success with imagination and understanding, unceasing scrutiny and vigilance will be required.

Ultimately much must depend on the interest taken in technical assistance by the scientific man and technologist. Clearly any proposals for a Commonwealth or international technical service should engage the close attention of their professional associations, to ensure that satisfactory conditions of service are laid down. Clearly, too, if the demands which technical assistance makes on trained man-power in Britain and in other advanced countries are to be accepted, steps must be taken to ensure that the limited man-power available is not wasted on projects which offer little prospect of success, whether through political, economic or technical reasons. It is perhaps through imaginative and sympathetic selection of enterprises, rather than grandiose schemes for new international agencies with financial resources geared to military expenditure, that the backward areas will be able to develop the resources which will both raise the standards of living for their own peoples and minimize the dangers to which the demands of increasing world population expose the whole world.

STABILIZING SELECTION IN EVOLUTION

Factors of Evolution

The Theory of Stabilizing Selection. By I. I. Schmalhausen. Translated by Isadore Dordick. Edited by Theodosius Dobzhansky. Pp. xiv+327. (Philadelphia: The Blakiston Company, 1949.) 6 dollars.

ALTHOUGH I. I. Schmalhausen's book appeared in Russian in 1947, and in an American translation as long ago as 1949, it has received rather little attention in Great Britain, and it still seems worth while to review it. It is a ponderous work, written in a style which, one suspects, was even before translation heavy and repetitious, and the translator has not succeeded in making it easy to read. But the labour brings rewards. The book contains accounts of most of the recent experimental and theoretical work on the genetical mechanisms of evolution; but it is not in this that its main value lies: indeed, better summaries of this material will be found in the well-known monographs of Dobzhansky, Huxley and others. Schmalhausen provides rather fuller references than most such publications to recent Russian work, which is not so accessible, and this already gives his book certain distinctive usefulness.

The main value of the work, however, lies in the particular point of view which Schmalhausen has derived from his studies as an embryologist, and which differentiates him from most of the other recent writers on evolution. He makes a consistent attempt to envisage the evolving animal, not as a mere adult form, nor as an assemblage of genes, but as a developing being characterized by a certain norm of reaction to its surroundings. This leads him to emphasize the conservative role of selection. He lays stress on the distinction between 'dynamic selection', which brings about changes in the animals submitted to it by favouring certain new types, and 'stabilizing selection', which perpetuates the norm by eliminating deviants. He points out that stabilizing selection does not merely conserve the *status quo*; it will actually entrench the prevalent and well-adapted norm, rendering its development more stable and less responsive to disturbing influences. It would have made Schmalhausen's thought clearer if he had distinguished these two aspects, both of which are included in his use of the term 'stabilizing selection'; as Simpson has pointed out in a review in the *Journal of Heredity*, it is also used in still other different senses.

Schmalhausen directs attention to the importance of stabilizing selection as a mechanism for the evolution of adaptations. He suggests that an originally variable but adaptive response to an environmental stimulus may become stabilized and will then eventually arise autonomously—that is, by heredity. Owing to the lack of precision of the general phrase 'stabilizing selection', it is not easy to make quite certain how Schmalhausen envisaged the passage from the 'acquired' to the 'inherited' status of the character. Sometimes he seems to be thinking along the lines of the theory of 'organic selection', suggested some fifty years ago by Baldwin, according to which an adaptive environmental response acts by enabling a species to occupy an otherwise unsuitable niche until such time as a mutation turns up which endows it with a hereditary adaptation. In other places he seems to imply, but perhaps never quite clearly states, what is surely the more fruitful suggestion, that if a response to an abnormal environment becomes stabilized in the sense of being rendered less susceptible to disturbing influences, this means that it will be less easily abolished when the abnormal environmental influence is removed, and will in this way pass from being dependent on the environment to being relatively independent of it. Similar ideas were put forward in a short article by me, using rather different terminology, at about the same time as Schmalhausen's book first appeared; but in this latter work they have received for the first time a full-length discussion against the background of the relevant embryological, genetical and evolutionary facts.

C. H. WADDINGTON

PROBLEMS AND POSSIBILITIES IN FOOD TECHNOLOGY

Advances in Food Research

Vol. 3. Edited by E. M. Mrak and George F. Stewart. Pp. xii+518. (New York: Academic Press, Inc., 1951.) 9.50 dollars.

THIS, the third volume of "Advances in Food Research", presents monographs on ten subjects. References, which total about fourteen hundred, usually bring information up to 1950; early work, however, is not neglected.

Two papers relate to discoloration of foodstuffs. M. A. Joslyn and J. D. Ponting deal with enzyme-catalysed oxidative browning of fruit products, which may be a serious problem to the manufacturer when fruit requires peeling or slicing. The varied enzyme systems involved are discussed, and suggestions for controlling the trouble in manufacture are put forward. The well-known 'browning' reaction which discolours products such as condensed milk is considered by J. P. Danehy and W. W. Pigman in an article on reactions between sugars and nitrogenous compounds and their relationship to certain food problems. The aldehyde–amine reaction is followed from its simplest form to the production of melanoidins and of protein-saccharide compounds. It is suggested

The [illegible] tive, and the printing and product[illegible] The use of regular hexagons for benze[illegible] to be commended. Only one formu[illegible] l as in error—that of terylene (p. [illegible] ersonalities of organic chemistry are [illegible] brief biographical footnotes that accom[illegible] st mention of a "named reaction", etc. The [illegible] appendix on the pronunciation (American a[illegible]) of organic chemical words which is scarcely necessary if the text is to be used in conjunction with a lecture course.

A chapter devoted to organic peroxides, autoxidation and antioxidants is a commendable innovation, while the chapter on organometallic compounds contains an account of the newer developments in organosilicon chemistry. The chapter on stereoisomerism contains an admirable introduction to the topics of absolute and relative configuration. The description of the boat and chair conformations of *cyclo*hexane as *cis* and *trans* forms (p. 562) is deprecated. The *cis–trans* terminology was introduced to describe the isomerism, about an ethylenic bond and within a single plane, exemplified by maleic and fumaric acids. The subsequent extension of this terminology to describe the isomerism in three dimensions of disubstituted *cyclo*alkanes, etc., was unwarranted, but has become sanctioned by long usage. The further extension of this terminology to include the boat and chair conformations of *cyclo*hexane would confuse fundamentally different phenomena and would seriously weaken the value of established *cis–trans* usage. This is a criticism of a point of detail, however, and the book as a whole can be warmly recommended as a reasonably priced text-book of organic chemistry for students in British universities. S. H. HARPER

LABORATORY TECHNIQUES IN THE TESTING OF MILK

Milk Testing

The Laboratory Control of Milk. By Dr. J. G. Davis. Pp. 260. (London: Dairy Industries, Ltd., 1951.) 15*s*.

THIS book is described in the preface as a "practical manual for the bench worker", but many, including the reviewer, will no doubt also keep it as a ready form of reference on all dairy subjects where laboratory technique of a specialized nature is required. The manual is not merely a collection of methods, for Dr. J. G. Davis has given the reader the benefit of his many years of experience both as a practical chemist and bacteriologist, and also as a technical director of one of the largest dairy companies in Great Britain. The methods for the control of the quality of milk are therefore one of the book's main purposes. Many of the methods embodied in British Standards have been quoted *in toto*. Since these are the result of collaborative study by dairy chemists, public analysts and independent analysts, they can be accepted as authoritative. Dr. Davis can quote from personal knowledge of the many discussions and tests which preceded the formulation of these methods, since he is a member of long standing of the relevant committees of the British Standards Institution.

Dr. Davis has described a number of interesting personal observations which may be new to the reader; for example, the experience of a milk having a 'disgusting' odour which changed to that suggesting mushrooms in a few hours, and which finally vanished completely. It is to be hoped that the bench worker will profit from the many references in the text, for these are a mine of information for the willing searcher. How many, however, will realize the possibilities of Meihuizen's oven, or trouble to look up the reference when told on p. 103, "For a description of an oven designed for the determination of moisture see Meihuizen (1929)"? Several tobacco laboratories and my own laboratory have adopted this oven, which passes evenly a forced draft of air heated, and if necessary dried, at a predetermined temperature over all the samples in a cylindrical oven, provision being made for evacuating if required.

Prominence has been given to the freezing-point depression as the most reliable guide to the presence of added water. Dr. Davis has given a well-reasoned and unbiased review of the literature on the subject, rightly pointing out the empirical nature of the Hortvet test. In his remarks on the use of sugar solutions for testing the accuracy of the thermometer, I could have wished that the operator in possession of a thermometer calibrated by the National Physical Laboratory were also told that, with the aid of such an instrument as a standard of temperature, sugar solutions could even more usefully be used as a check on technique. The false view is currently held in some quarters that the freezing-point depression of milk is measured in 'Hortvet' degrees. On the contrary Hortvet used, as his standard, thermometers calibrated by the U.S. Bureau of Standards on the International Temperature Scale. When an empirical test relies on accurate standardization of apparatus, technique, etc., and cannot be checked by any absolute method, it is of fundamental importance that the one factor which can be standardized independently, namely, the thermometer, should have the benefit of this standardization.

As might be expected from a bacteriologist of Dr. Davis's standing, particular attention has been devoted to modern bacteriological testing of milk. His summary of comparisons of various bacteriological tests in the form of table on p. 119 is the outcome of many years of careful observation. The resazurin test, of which Dr. Davis has made a special study, is described with a wealth of practical detail, and with many hints on the correct interpretation of results. An unusual feature of such a book is a chapter on the organization and equipment of a dairy control laboratory, and the author has obviously given careful thought to the suitable design of such laboratories. Many of his ideas could, in fact, usefully be employed in any modern analytical laboratory.

For a book so packed with data, the errors are comparatively few, and fortunately these will not worry the bench worker. On p. 31, fat is described as having a specific gravity of 0·93 per cent. While sodium thiosulphate is employed to break up any mercury-amino body in Kjeldahl determinations, it is scarcely necessary to use it with a copper–selenium catalyst (p. 59). The inexperienced laboratory worker might be confused by the wording in the directions for preparation of standard solutions, as in some cases this suggests that the reagent is added to a volume of water and not dissolved and the solution bulked to the volume (pp. 230, 231).

The book is profusely illustrated and contains such a mass of useful data that it will surely find an indispensable place in the library of all dairy laboratories and form a most ready guide to all analysts who have to test milk and its products.

J. KING

Encyclopedia on Cathode-Ray Oscilloscopes and their Uses

By John F. Rider and Seymour D. Uslan. Pp. vii+982. (New York: John F. Rider Publisher, Inc.; London: Chapman and Hall, Ltd., 1950.) 75*s.* net.

THIS impressive volume, in common with most Rider publications, is not an advanced textbook. It has been compiled for those users of oscilloscopes—students, teachers and others—who have had a limited training in electronics and who can profit by obtaining a thorough understanding of the principles involved in the design and application of an instrument that is nowadays one of the most important items of apparatus in the lecture room, laboratory and factory.

The first half of the book contains a thorough account of the construction of the cathode-ray tube and the design of the associated circuits, as employed in American commercial equipment. The British reader may find the continual reference to American types of cathode-ray tubes and valves rather disconcerting; but this is more than compensated for by the clarity of the exposition. The more advanced reader will notice that there is no reference in the chapter on time bases to the Miller type of circuit that is frequently used in British oscilloscopes, and that a description of the wide-band chain amplifier has been omitted. No doubt these omissions will be corrected in the next edition.

The second section of the book covers the main applications of the oscilloscope to the testing of radio receivers and transmitters and to the measurements commonly made in the laboratory and factory. These chapters are well illustrated with oscillograms showing the wave-forms due to typical faults in the circuits under test.

There is a long chapter illustrating the wave-forms of oscillations containing harmonics up to the sixth, and this should enable the reader to identify the various wave-forms he may encounter in his experimental work. The book concludes with a chapter giving the circuits and a brief explanation of each of some seventy commercial oscilloscopes of American manufacture.

Although a book covering such a vast subject as oscillography cannot contain details of every aspect, the authors have produced a volume that will prove to be of great value to those for whom it has been compiled. G. E. ASHWELL

Vorlesungen über Theoretische Physik

Band 4: Optik. Von Prof. Arnold Sommerfeld. Pp. xvi+390. (Wiesbaden: Dieterich'sche Verlagsbuchhandlung Inh. W. Klemm, G.m.b.H., 1950.) DM. 18.50.

THIS volume on optics follows the other parts of Sommerfeld's lectures on theoretical physics in its mathematical elegance and clarity, while never allowing the reader to forget the connexion of the mathematical problems with physical reality. The material is deliberately arranged in a somewhat unorthodox sequence. The theory of plane waves and plane interfaces (including refraction, reflexion and interferometers) is followed by relativistic theory and the optics of moving media. Dispersion theory is treated using the results of wave mechanics of the atom, and the section dealing with phase, signal and group velocity is of very convincing simplicity and completeness. Crystal optics is covered fairly briefly, but two full chapters deal with diffraction, one of the subjects to which Sommerfeld made decisive contributions. There is a short list of problems, mostly to derive generalizations of results mentioned in the text, and instructive notes on their solution.

In the review of earlier volumes (see *Nature*, 168, 887; 1951) I remarked on the desirability of having the series completed and of making a translation into English. Several correspondents have since informed me that the last volume is in course of publication, and that a translation is being prepared.

R. E. PEIERLS

The Apple and the Spectroscope

Being Lectures on Poetry designed (in the main) for Science Students. By T. R. Henn. Pp. xix+166. (London: Methuen and Co., Ltd., 1951.) 12*s.* 6*d.* net.

THOSE who devote their lives to the pursuit of natural science often realize how little they know of English prose and poetry, which contribute so much to the thought of people educated in the humanities. A few years ago, a group of young Cambridge scientists asked for instruction during the 'long vacation' in English literature and language. The series of lectures that was arranged proved very popular, and the lectures given by Mr. T. R. Henn as part of this course have now been published. The first eight chapters are about poetry, and an appendix contains the poems and passages examined in the text. Two chapters are entitled "Notes on a Background to English Literary History", with an appendix of authors and their dates. The concluding chapter, full of interesting reflexions and suggestions about reading, is accompanied by a list of works suggested for casual reading.

This delightful little book can be recommended to those who wish to know something of the qualities which distinguish good poetry and prose. It is full of interest in its matter and approach, while its consideration of the significance of words may prove of practical value to those who write scientific papers and lecture notes. There are some pleasing illustrations, and it is easy to see why the author's lectures to Cambridge scientists were so popular.

H. H. T.

The Bird Lover's Week-End Book

By Eric Hardy. (Week-End Library.) Pp. 444. (London: Seeley, Service and Co., Ltd., n.d.) 15*s.* net.

THIS "Week-End Book" is an ambitious volume, its author trying to cover a very big field. The first chapter on the bird-watcher's year is a lengthy review of the passing months as seen by the author and recorded in weekly notes. He then gives a key to bird identification under such headings as "What the bird looks like", "the bill", "upper parts" and so on. It will be gathered that the book is written for the amateur ornithologist, and the beginner at that. There is no doubt that the tyro will find it a real help.

The chapter on the bird-watcher's equipment contains much useful information on subjects varying from binoculars to bird-baths. Reference to subjects is here facilitated by their alphabetic arrangement. Bird haunts and bird holidays are among the topics dealt with, and there is a long chapter on "nicknames" of British birds. The reader wanders on through chapters on migration, British birds abroad, etc., and winds up with a glossary of the bird-watcher's terms. There is no doubt that the amateur ornithologist spending a week-end in the countryside will find this a helpful book. FRANCES PITT

PROPERTIES OF VITREOUS WATER

By Dr. J. A. PRYDE and Dr. G. O. JONES
Department of Physics, Queen Mary College, University of London

THERE are a number of analogies[1] between the structure of water and that of vitreous or liquid silica, and many suggestions exist in the literature to the effect that water (like silica) can exist in the glassy or vitreous state. Vitreous pure water has not previously been obtained in bulk (though aqueous solutions can often be supercooled into glasses), but very thin films of water in an apparently amorphous non-crystalline state well below 0° C. have been obtained in various ways—for example, by very rapid cooling in liquid air[2,3], or by deposition from the vapour on a surface cooled below about $-100°$ C. Burton and Oliver[4] showed that films formed by the latter method gave X-ray diffraction patterns typical of liquids and glasses. However, on heating, crystallization—or 'devitrification'—occurred, being complete at $-80°$ C. As reported by Brewer, Cwilong and Dobson[5,6], deposition of very thin layers of this 'vitreous ice' on the cooled thimbles of hygrometers is a common and unwanted occurrence in meteorological experiments when the thimbles are below about $-100°$ C.

The intention in the present work was to attempt to prepare sufficient vitreous water to allow some of its properties to be determined, especially its 'glass transformation temperature' T_g[7,8]. As shown in Fig. 1 (after Simon[9]), substances which form glasses show large discontinuities in first-order derivative properties such as the specific heat over a narrow range of temperature located by T_g. Below T_g the substance is conventionally called a glass, is not in internal equilibrium, and its first-order derivative properties are nearly identical with those of the crystal. Above T_g it is a (metastable) supercooled liquid, and its properties are continuous with those of the normal liquid above the freezing point. Of course, both as supercooled liquid and glass the substance is unstable relative to the crystal, and crystallization may occur at any temperature. For substances which form glasses, this is usually very slow except over a certain temperature-range, and if T_g is well below this temperature-range, as it is for most inorganic oxide glasses for example, it is possible to carry out real property/temperature measurements on the (metastable) equilibrium liquid over wide ranges of temperature well below the freezing point. (Sometimes, as with glycerol, devitrification is so slow at all temperatures that these measurements can be extended continuously down through the freezing point as far as T_g.) The many anomalous properties of water make such measurements especially desirable.

We must emphasize that in our experiments on water, carried out well below $-100°$ C., the temperature was always below that at which the rate of nucleation is a maximum for this substance. Here, high viscosity is the barrier to crystallization, and the onset of crystallization sets an upper limit of temperature above which the experiments cannot be extended. In the experiments of other workers on the properties of supercooled water in bulk between the freezing point and about $-20°$ C.[10], or on condensation in cloud chambers down to about $-40°$ C.[11], maintenance of the liquid state depends essentially on the absence of nuclei, and the onset of crystallization sets a lower limit of temperature upon the measurements. The properties of the liquid between about $-100°$ and $-40°$ C. seem to be almost inaccessible to experiment, although droplets of liquid 'dew' can be formed from the vapour within this range on certain types of clean surface and persist for a short time[12].

Experimental Methods and Results

In the first experiments, carried out by one of us (G. O. J.) at the Clarendon Laboratory, Oxford, in collaboration with Prof. F. E. Simon, attempts were made to produce quantities of the order of one gram of vitreous water by rapidly cooling in liquid oxygen a block of porous copper containing water held in a fairly fine state of sub-division (of the order of a few microns). (It was hoped that a substantial proportion of the pores might be free of freezing nuclei so that crystallization could not spread throughout the liquid.) The block and its contents could afterwards be quickly transferred to a vacuum chamber for controlled heating. On the first occasion, the heating curve showed a quite sharp decrease in slope, corresponding to a sudden increase in heat capacity, at $-147 \pm 2°$ C. As soon as this was obvious, the block was re-cooled to liquid-oxygen temperature and a new heating curve taken, again with the same result. We believe that these were real observations of the characteristic behaviour of the glass transformation, but cannot attach much importance to the actual estimate of T_g because of the rather fine state of sub-division of the water and the possibility that it contained impurities such as the products of reaction with copper.

Unfortunately, these observations could not be repeated. In all later attempts the water formed ordinary ice in the pores—as could be confirmed by observing the 'flat' in the heating curve at 0° C. It was suspected that the copper must now be 'seeded' by some particularly effective type of nucleus for crystallization, so new samples were used. A 'book'

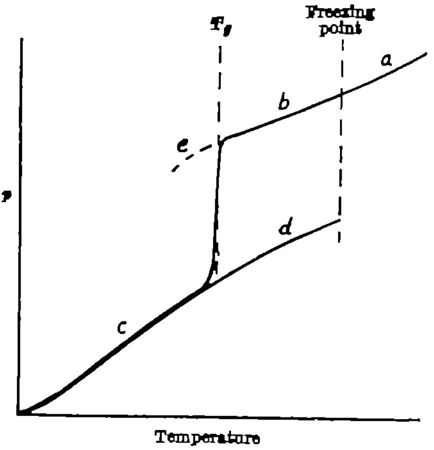

Fig. 1. Specific heat–temperature curves for a substance in the following forms (after Simon): (*a*) liquid, (*b*) supercooled liquid, (*c*) glass, (*d*) crystal, and (*e*) start of equilibrium (metastable) curve for supercooled liquid

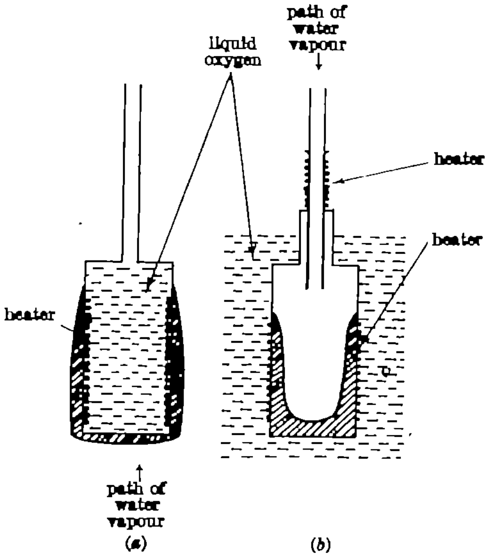

Fig. 2. Calorimeters used for measurement of thermal properties of vitreous water, showing method of deposition from water vapour

of nickel foil holding about a gram of water between its leaves was also tried, and many other variations introduced in the procedure (such as the use of stagnant liquid oxygen or nitrogen below their boiling points for more rapid cooling, and the application of strong heating in vacuum to attempt to destroy 'seeds' in the pores) without any further success.

In all subsequent experiments the method of deposition from the vapour was employed. The water was always double-distilled and freshly boiled before use. Fig. 2 shows two types of calorimeter used, and indicates how the temperature was maintained at that of liquid oxygen during deposition. The liquid oxygen could then be removed and the space surrounding the calorimeter evacuated for controlled heating. The advantage of type (*a*) was that the layer of water-substance, being on the outside, could be seen (it was noted that films prepared in this way were transparent at small thicknesses but imperfectly so at greater thicknesses). Type [illegible] was, however, more suitable for quantitative measurements because it enabled a known quantity of water to be deposited, and to be retained throughout the experiment; for greater accuracy in measurement, a radiation shield was used in conjunction with this calorimeter.

No behaviour characteristic of the glass transformation could be detected in any of a large number of such runs (some extending upwards from about −210° C.); but in every case an evolution of heat began when the calorimeter reached −129 ± 1° C., causing a rapid rise in temperature. This was clearly an irreversible phenomenon, since it was not repeated after re-cooling. We attribute it to crystallization into ordinary ice (ice I)—a process which at this temperature would, of course, be irreversible—because no further irreversible evolution or reversible absorption of heat occurred until the temperature reached 0° C. This is of interest in view of reports[12,13] that another form of ice (with cubic symmetry) can be formed by deposition from the vapour on cold surfaces.

Crystallization at −129° C. was observed twenty-nine times in all. The quantity of heat evolved per unit mass of water varied from run to run between about 2 and 7 cal./gm., smaller values being observed with thicker layers. The specific heat of the water-substance below and above the temperature of the irreversible crystallization was found to be the same, within the possible errors of measurement (a few per cent), and agreed to the same degree of accuracy with known values for crystalline ice at the same temperatures.

As a control, the whole experiment was performed twice with pure ethyl alcohol, which is known to form a glass for which T_g is −178° C.[14]. It was found that a glass was obviously formed by deposition from the vapour at the boiling point of liquid oxygen, and the measured values of T_g, and of c_p below and above T_g agreed well with the published values (this is of interest because a glass deposited from the vapour at a given temperature might be expected to differ from one formed by supercooling the liquid to the same temperature). Crystallization occurred at −150° C. (the normal freezing point is −117° C.) with the evolution of a much greater quantity of heat than observed by us with water.

Discussion of Results

Crystallization. The remarkable constancy of temperature at which crystallization occurred might at first suggest the existence of a real transition point at this temperature. In fact, the change was found to be irreversible; indeed, a reversible transition from a low-temperature to a high-temperature modification cannot be accompanied by an evolution of heat. (The existence of characteristic temperatures for irreversible crystallization in particular circumstances has frequently been reported[5,8,10,11,15], but has apparently not been observed at temperatures below that at which the rate of nucleation is a maximum. It is normally thought to be due only to the fact that rates of crystallization varying very rapidly with temperature may cross the 'time-scale' of observation over a very narrow temperature range.) The actual temperature (−129° C.) is somewhat lower than the values (−90° to −80° C.) usually reported for the temperature at which crystalline ice appears during the heating of layers of 'vitreous ice' on the thimbles of dew-point hygrometers as used for observations on very dry air. However, as pointed out to us by Dr. A. W. Brewer, of the Clarendon Laboratory, Oxford, these layers are usually only of the order of molecular thickness and the ice cannot be seen until it has collected (by migration over the surface) into much thicker localized aggregates; it is not surprising that a higher temperature is required for an effective rate of migration.

The estimates of the latent heat of freezing at −129° C. varied from one run to another, as we have seen, being of the order 2–7 cal./gm. Before we can judge whether these are reasonable values, we have to know something of the form of the specific heat/temperature curve for liquid water below 0° C.—a difficult extrapolation since the specific heat has a minimum at about 35° C. and is still increasing with falling temperature at 0° C. Making use of Simon's suggestion[8] that the curve of specific heat against temperature for the equilibrium (metastable) liquid should be drawn to the origin in such a way that the entropy at absolute zero becomes the same as that of the crystal (see Fig. 1), we have a means of 'normalizing' the hypothetical curve. It is reasonable to assume also that the specific heat of the liquid does not fall below that of the crystal. Drawing the two extreme curves which, while meeting these conditions, give the largest possible difference between the two estimates that they provide of the latent heat at $-129°$ C., we arrive at values of about 20 and 40 cal./gm. If the liquid is, in fact, not in its metastable equilibrium state but is a glass at this temperature, the latent heat of freezing would be increased. We are forced to conclude, therefore, that the samples of water in our experiments were only partly vitreous, being, in fact, like badly devitrified pieces of glass (this was indeed their appearance). This conclusion follows rather obviously also from the fact that the amount of heat evolved per gram varied from one run to another, being much smaller than that observed for alcohol, and apparently depending on the thickness. It is known that the result of deposition from the vapour is very sensitive to the condition of the surface, and it would be expected to depend also on the speed of deposition. The 'latent heat of sublimation' to be dissipated is very large, and with a growing film of glassy substance of very low thermal conductivity the danger of local crystallization at 'hot spots' would increase. Better results might be expected if it were possible to deposit layers over very much longer times than those (of the order of hours) employed by us.

Glass Transformation. If we were to accept the results of the present specific heat measurements at their face value, we should conclude that T_g was not below the temperature at which crystallization sets in (since c_p for the deposited layer is the same as that of the crystal and shows no discontinuity) and was therefore impossible to locate exactly. It can scarcely be much above this temperature, and the two temperatures must therefore be quite close to each other, since a certain amount of mobility is possible at T_g—the temperature at which the adjustments necessary to reach configurational equilibrium can occur rapidly. Indeed in silica—structurally the closest copy of water—it is very difficult to conduct experiments in the transformation region because of devitrification. There is an element of doubt in our conclusion because it seems clear that only a fraction (say, between one-twentieth and one-third) of the material in our samples was actually vitreous, and it is by no means certain that the discontinuity in specific heat of the vitreous part could have been detected.

Fortunately we have a confirmatory estimate from the work of Kobeko, Kuwshinsky and Shishkin[16]. They pointed out that water as an impurity raised the value of T_g of ethyl alcohol ($-178°$ C.) but lowered it in the case of glycerol ($-88°$ C.). The value of T_g for water itself would therefore probably lie between these two temperatures. Moreover, T_g for pure hydrogen sulphate was the same as for a mixture of this substance with water of composition $H_2SO_4.2H_2O$. They therefore proposed this value, $-127°$ C., as T_g for water. Kobeko had previously shown[17] by several examples that when mixtures of two substances in any proportions could be obtained as glasses, the value of T_g for the mixture varied smoothly and monotonically with composition, and we do not find any difficulty in accepting this estimate as being at least nearly correct. (There is no direct relation between the phenomena of glass transformation and crystallization, and no reason to doubt the reality of T_g for a substance because it cannot easily be obtained as a glass.) Our own estimate ($-147°$ C.) from the first experiments with porous copper is lower, as would be expected if the water contained impurities, in themselves not glass-formers. It seems reasonable to assume that T_g for water lies at any rate in the range $-150°$ to $-125°$ C.

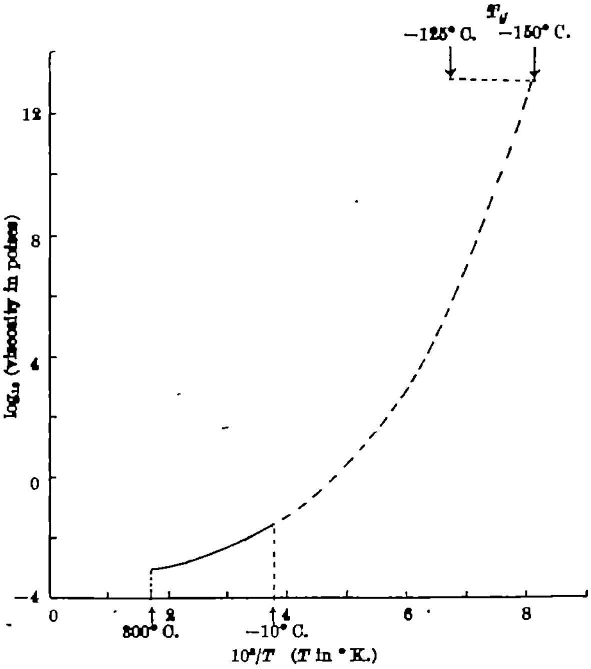

Fig. 3. Viscosity-temperature curve for water, extrapolated to T_g

Structure of Water and Mechanism of Viscous Flow. The above estimate of T_g leads to certain conclusions of interest. It is a quite general observation[8,18] for all glasses that the viscosity at T_g is of the order 10^{13} poises. This enables us to locate another part of the viscosity/temperature curve for water, as shown in Fig. 3, where $\log_{10}$ viscosity is plotted against reciprocal absolute temperature. The short full line represents values obtained[18] in the range $-10°$ to $300°$ C., and the broken line is an extrapolation drawn to meet the value corresponding to 10^{13} poises at $T_g = -150°$ C. The slope of this curve is usually regarded as an 'activation energy', and it will be seen that its value, which increases from about 1·5 to 5 kcal./gm. mol. over the temperature-range covered by the experiments, must continue to increase very

* Estimated from vapour-pressure data

considerably as the temperature falls further. We estimate its value at T_g as greater than 16 kcal./gm. mol. (a minimum figure obtained by a linear extrapolation between 0° C. and T_g); it will be noted that this is considerably greater than the latent heat of evaporation (9·7 kcal./gm. mol. at 100° C.).

It is well known[20-22] (see also table) that the activation energy for viscous flow, $E_{\text{visc.}}$, is large and increases continuously with falling temperature for liquids which are able to form glasses. These liquids are characterized by low co-ordination and markedly 'structural' nature and owe their coherence to strongly directed bonds such as the 'hydrogen bond' (in water, alcohols, etc.) or the ionic-homopolar Si-O bond (in silica). As shown by A. G. Ward[20], the increase of $E_{\text{visc.}}$ with falling temperature implies an increase in structural character—a change actually observed by Bernal and Fowler[23] in X-ray studies on water.

Values of $E_{\text{visc.}}$ greater than the latent heat of evaporation ($L_{\text{vap.}}$) do not appear to have been reported previously, on account of the difficulty of measuring $E_{\text{visc.}}$ for low-temperature glasses and $L_{\text{vap.}}$ for high-temperature glasses. Fortunately, however, the viscosities of three alcohols have been measured nearly to T_g[24], and in the accompanying table we list our own estimate, made from the published graphs, for $E_{\text{visc.}}$ at T_g for these liquids, together with values of $L_{\text{vap.}}$ and some other data of interest.

It will be seen that in *n*-propyl alcohol, *iso*-butyl alcohol and glycerol, as in water, $E_{\text{visc.}}$ can greatly exceed $L_{\text{vap.}}$ at low temperatures (the variation in $L_{\text{vap.}}$ with temperature is relatively small and does not affect the argument). This supports the suggestion of various authors[20,21,27,28] that the flow process in these liquids involves the breaking of strongly directed bonds rather than the movement of molecules. (In 'normal' liquids such as the metals, 'rare gases', non-polar organic substances and ionic salts, $E_{\text{visc.}}$ is always much smaller than $L_{\text{vap.}}$—usually about 1/3–1/4 of its value, or 1/8–1/25 in metals.) In the case of silica, $E_{\text{visc.}}$ at T_g is about twice the energy of the only type of bond present, the Si-O bond (~90 kcal./gm. mol.), and for water and these alcohols it is 3–4 times greater than the strength of the hydrogen bond from hydroxyl groups (6–8 kcal./gm. mol.) which is assumed to be responsible for their cohesion[20-31]. In glucose, which has a complicated molecule containing five hydroxyl groups, the value of $E_{\text{visc.}}$ is remarkably high.

Conclusion and Summary

In spite of the great difficulty of producing completely vitreous pure water, there is evidence that under favourable conditions water forms a glass, with the transformation temperature T_g lying between −150° and −125° C. The main implication of this conclusion is that the increase in structural character of water with falling temperature, already detectable above 0° C., must continue to a very marked extent as the temperature is lowered still further. As in other liquids containing directed bonds, the value of activation energy for viscous flow can exceed the heat of evaporation and the strength of a single bond by a large factor.

An unexpected result is that specimens of glassy water containing varying proportions of crystalline ice complete their crystallization (apparently into ice I) precipitately when the temperature is raised to −120° C.

We acknowledge the interest and collaboration of Prof. F. E. Simon, of the Clarendon Laboratory, Oxford, in the early stages of this work, and later the help and facilities given us by Prof. H. R. Robinson, at Queen Mary College, London, and the careful work of Mr. W. A. G. Baldock in making the calorimeters used in the experiments. We are indebted to the Central Research Fund of the University of London for the loan of apparatus, and to Imperial Chemical Industries, Ltd., for a grant-in-aid.

FACTORS INFLUENCING CHANGE IN HUMAN BEHAVIOUR

A FULL morning's session at the recent Belfast meeting of the British Association was devoted to the problems of "Resistance to Change", more especially resistance to the application of well-founded scientific knowledge in industry and agriculture. In the first half of the morning some of the more general questions were discussed by Section J (Psychology); in the second part of the proceedings, this Section joined with Section M (Agriculture) in a symposium on resistance to change in farming. Most of the speakers were more particularly concerned with the problems encountered by research, educational and advisory services.

Opening the general subject, Prof. C. A. Mace (Birkbeck College, London) developed the thesis that much of what is called 'resistance to change' is, in fact, failure in the process of communication. The sources of failure are not entirely at the receiving end; some are in the process of transmission. Quoting Prof. Georges Friedmann's observation that "there has been no technological revolution in most of the professions", Prof. Mace went on to explore the prospects of such a revolution in the educational and advisory services. This revolution is coming, he said, through the use, not of precision machines, but of precision techniques. He cited the B.B.C. "Audience Research", a recent report on "Foremanship Training" by A. J. Flook, and a study of "Human Relations Training" by P. Castle, of the National Institute of Industrial Psychology. The essential features of these new techniques of 'precision education' are threefold: the communication, instead of being diffused, is directed to a selected target audience; it is adapted in content and form to actual needs empirically ascertained; and by suitable 'feed-back' devices the impact of the communication is accurately assessed. As the word 'broadcasting' has come to be almost a synonym for 'mass communication', broadcasting the thing is "becoming a technique for focusing a beam of specific intelligence upon a particular public with particular ends in view". The importance of these developments lies in the generality of the principles involved. These principles apply to every form of communication from the poster as simple as "Mind how you go" to the whole curriculum of studies for a B.Sc. degree. They apply to every form of advisory service. Advisory services are essentially concerned with combating resistance to change; but sometimes they themselves are resistant to suggestions for change in the methods they employ. They themselves need to be serviced by advisory research in their problems of communication.

Passing reference was made in the opening paper to certain critical phases in the life of an individual at which variations occur in his "coefficient of resistance to change", and one of these phases was the subject of the second paper, in which Miss M. Woodward (Bedford College, London) reported evidence of "changes in social participation following the birth of a child". In the respects considered, this is a more important event than that of marriage. A survey was made of the membership of societies, the informal relations with friends and working associates, and the leisure pursuits and the interests of 186 women attending a clinic in a dormitory area of London. Impressive facts were adduced regarding the general decrease in a mother's social activity outside the immediate family circle after childbirth. The consequent sense of isolation and increased dependence on the husband for the satisfaction of social needs may, it was suggested, place a serious strain upon marital relations. The findings in this survey acquired additional significance in the context of the symposium. Later speakers were to stress the importance for the diffusion of change of social participation in the life of a group larger than the immediate family circle, and Miss Woodward's observations may contribute to the explanation of the characteristically conservative influence of family life as such.

In the second half of the morning's session, Mr. J. M. Mogey (director of the Oxford Pilot Social Survey) introduced the discussion of resistance to change in agriculture by a historical and anthropological analysis of factors affecting rate of change in the agriculture of Northern Ireland. Owing to physical and historical conditions, Northern Ireland is a country of small-scale farming, and one in which the basic social unit is the farming family. These units have in part been informally organized in clusters of from ten to twelve farms co-operating on the basis of ties of kinship and proximity. New ideas and techniques filtered through to the ordinary farmer only in so far as they fell within the economic potential of the single small farm. In the face of resistance arising from a tradition of informal co-operation, government action in wage control and the promotion of marketing schemes has had only a limited effect. The resistance to official action has been greatest in respect of agricultural education. There has been a failure to work through the informal groups of the countryside. The conclusion was drawn that in a community of small owner-occupiers improvements in farm techniques must be demonstrated by equals. A raising of the level of skill can be expected only through local experiments on the basis of a complete farm. A few successful farms assisted by an advisory service scattered over the countryside and open to visits from neighbours, with the farmer himself explaining the methods employed, would arouse interest and create a desire for more instruction.

Prof. R. Rae (director of the National Agricultural Advisory Services) followed with a discussion of the farmer's attitude to technical advances. He placed high among the factors that influence the farmer's attitude the prospect of reasonable profit from the business of farming. The success of an advisory service depends on the general standard of education of the farmers, and on the introduction of agricultural science to young men in the formative period of their lives. He, too, stressed the importance of demonstrating new methods on farms open to visits from neighbours. He thought that there is no section of the community more receptive to new ideas than the top-grade farmer. In the lowest grade little can be done. In this group there are too many who suffer from the combination of two disabilities old age and lack of experience. It is the middle group, the majority, that offers the greatest promise to the advisory services. Farming is essentially a complicated business, and the farmer must be a business man able to organize labour, and so something of a psychologist. In addition, he must be something of an engineer and an economist and must also be a craftsman; and it is an advantage for him to have some understanding of agricultural science. It is this complexity of requirements which constitutes the reason for the existence of advisory services.

The session concluded with a paper by Dr. Roland Harper (University of Leeds) on psychological aspects of the application of new knowledge and techniques in agriculture. Dr. Harper was concerned with the problems arising in passing scientific knowledge "down the line" from the research laboratory to the farm. The expression brought out the close analogy between the problems of an advisory service and those of the management consultant in promoting communication from higher management to the worker at the bench. It is mainly the psychological factors, Dr. Harper suggested, which prevent the established results of agricultural research from being applied with expedition. He proceeded to review some of the more relevant psychological studies—Lewin's investigation of factors influencing food habits, Ryan and Gross's study of the diffusion of seed corn in Iowa, and Wilkening's "socio-psychological approach to the study of the acceptance of innovations in farming". Expanding the survey, Dr. Harper elucidated some of the general psychological concepts relevant to the problem—motivation and attitudes, social participation and the cognitive aspects of communication. He concluded with some practical suggestions. His analysis reinforced the arguments of previous speakers for operating through informal groups. Much more, he thought, could be done through the guided discussion group. Special emphasis should be placed on means for assessing the success or failure of the methods used by advisory services. He advocated co-operative research in Great Britain similar to that which he had cited from the United States. He suggested that greater attention should be paid to the attitudes of farmers towards new procedures, and very special attention given to their "uninhibited reactions to our present advisory services".

Contributions to the discussion from the floor were, very appropriately, in the form of such uninhibited reactions of the practical farmers themselves. They reinforced what Dr. Harper and others had said regarding the importance of understanding the needs of those for whom advisory services are provided. It seemed clearly to emerge that scientific advice administered neat is apt to be ineffective. The scientific advisory officer needs to be not only a man of science but also something of a management consultant, competent to advise the farmer in costing the procedures suggested, and able to assist him in adapting general principles to the special circumstances and the particular economy of his farm. This conclusion was in close accordance with an opinion expressed in a conference on farm management organized by the British Institute of Management earlier in the year. A combined scientific and management advisory service is what is most needed. Such a service is of especial importance for the small farmers who comprise the vast majority of those for whom these services are provided.

There would appear, too, to be a substantial body of opinion which favours more detailed and intensive advisory services to a smaller number of farms in preference to a wider service spread more thinly. If it is indeed true that farmers learn more readily from practical demonstrations of successful farming than from the spoken or written word, a well-distributed selection of farms serviced in detail might be more effective than more diffused methods. It is agreed, however, that, whether focused or diffused, advice must be followed up by inquiries whether the advice has been acted on: If not, why not; and if so, with what effect? Follow-up provides the 'knowledge of results', the 'feed back', upon which success depends; and to make this a routine procedure may be more useful and less expensive than the organization of special attitude and opinion surveys of consumers' needs and reactions.

It is of interest to note that, although the symposium was especially concerned with advisory services to the farmer, the policies and principles discussed were of universal application. Regulations continue to multiply, but in all modern civilized societies there is a greater proportionate increase in the use of methods based on advice and persuasion. Advisory services are developing for agriculture, for building and most of the manufacturing industries, and the ordinary citizen has an immense variety of advisory services concerned with his health, his education, his vocational needs, his civil rights and responsibilities. In all these advisory services there is a need for better understanding of the sources of friction and resistance in the channels of communication from the laboratory or the field station to those who have to turn the results of scientific research to practical account.

This was the first joint meeting of the Agriculture and Psychology Sections in the history of the British Association; but with the continued expansion of research and advisory services, it may well be the precursor of many symposia on the psychological aspects of the technique of applying the methods and results of science to human affairs.

BIOLOGICALLY SIGNIFICANT MACROMOLECULES

A MEETING of Section B (Chemistry) of the British Association took place in Belfast on September 9 before a packed audience under the chairmanship of Prof. M. Stacey (professor of organic and biological chemistry in the University of Birmingham), the subject being "Biologically Significant Macromolecules".

Prof. Stacey spoke on "Polysaccharides of Medical Importance". In the normal functioning of the animal body the synthesis of macromolecules and their subsequent breakdown is of obvious importance. Continuous biological polymerization and depolymerization are essential in growth processes and provide a fascinating study especially in the polysaccharide field. It is perhaps not surprising that the medical applications of complex carbohydrates are becoming of increasing importance.

A good deal is now known regarding the so-called immunologically specific bacterial polysaccharides, especially in the Salmonella and Pneumococcus groups. In the pneumococcus the polysaccharides occur mainly on the surface of the bacterial cell as a capsule from which they may pass into solution in the growth medium of the organism. When they penetrate into the animal body, they stimulate the production of immune proteins, and *in vitro* in very high dilution they give rise to a specific precipitate on reaction with homologous immune serum. There are more than fifty of these specific polysaccharides, each possessing a different chemical structure, though their physical properties may be similar. A special characteristic is that many of them possess hexosamines and hexuronic acids, in addition to hexoses, as constituent building-units. During recent years, Prof. M. Heidelberger and his colleagues in the United States have shown that the pneumococcus polysaccharides free from protein will immunize human beings against infection, and a mixture of polysaccharides may be used as a prophylactic vaccine against pneumonia. The protection will last up to twelve months, and in large communities the incidence of many types of pneumonia can be lessened.

Vaccines against typhoid, dysentery and cholera, etc., mainly owe their immunizing properties to the presence of a complex carbohydrate residue which contains glucosamine and galactose and which is conjugated to phospholipids and amino-acids.

Seven distinct polysaccharides have been obtained from the mycobacterium which causes tuberculosis in humans, and their specific serological reactions are being studied. When freed from protein, they do not appear to give rise to any immunity. When polysaccharides having molecular weights of the order of a million are degraded by acid or by enzymes, they can often be injected into animals without setting up any immunity in the host. They may, however, cause skin reactions in sensitive individuals, and some forms of allergy can be traced to distinct chemical structures or even groupings, though protein constituents or nucleoproteins are more likely to be incriminated in such cases.

The bacterial polysaccharide dextran has been degraded by a variety of means, and a fraction having a molecular weight not greater than a hundred thousand has been used successfully as a blood plasma substitute. It is being used extensively, particularly in Britain and Sweden, in conjunction with natural plasma against shock, burns and loss of blood. The polysaccharide is composed entirely of glucose units, and it is completely metabolized in the body within a few days.

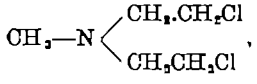
Another valuable dextran product is the sulphate made from a fraction having a molecular weight of about twenty thousand. This is essentially non-toxic, and it prevents the coagulation of blood and is likely to become valuable in post-operative work and in thrombosis. It has an action like heparin, the natural anticoagulant. Blood-group substances present in the red cells and tissues of individuals of groups A, B or O, etc., are mainly of a polysaccharide nature. Their study by chemical means will give valuable information on inheritance characters.

Body 'building' constituents, such as bone, cartilage, tendons and joint fluids, are polysaccharides containing hexuronic acids, amino-sugars, sulphate and acetyl residues. They can be depolymerized by enzymes such as hyaluronidase, lysozyme, etc., and the state of polymerization appears to be important in certain rheumatic conditions. The enzymes may be under the control of cortisone or the adrenocorticotropic hormone, and it is of great importance to make structural studies in the group.

The biosynthesis of one macromolecule may depress that of another type in its immediate vicinity. There is some evidence that certain bacterial polysaccharides will suppress the formation of the nucleoproteins in some tumours, and efforts have been made for some years by Dr. M. J. Shear and his colleagues in the United States to apply this in the attempted cure of some forms of cancer. In a somewhat similar way microbial and other polysaccharides may cause the slowing-down or may suppress the growth of viruses such as the influenza virus. Physical factors come into play, and efforts are being made to investigate virus multiplication and inhibition along these lines.

Dr. B. E. Conway (Chester Beatty Institute, London) then gave an account of the "Physical Chemistry of Deoxyribonucleic Acid". The probable importance of deoxyribonucleic acid conjugated with basic proteins to form the chromosomal nucleoproteins and in the process of cell division was stressed, and the action of ionizing radiations and radiomimetic substances such as the 'nitrogen mustards' on dividing cells was briefly indicated. Attention was directed to the great amount of information to be gained by studying the effects of these agents on isolated deoxypentosenucleic acid. However, prior to investigations of this type it is necessary to have some information concerning the physical condition of nucleic acid solutions. Dr. Conway briefly reviewed experimental studies by various workers in which the ultracentrifugal, diffusion, viscosity, streaming birefringence and light scattering behaviours were observed. These experiments led to a picture of nucleic acid solutions as consisting of a dispersion of highly elongated, fairly rigid particles, between which there is considerable electrostatic and/or van der Waals' interaction. The marked effect of simple uni-univalent salts on the viscosity of the nucleic acid, together with the observation of Signer and Schwander that the orientation of the nucleic acid particles in streaming birefringence experiments is independent of sodium chloride concentration in the solution, emphasizes the apparent importance of electrostatic interactions between particles in nucleic acid and its solutions. In addition to these effects with simple salts, the addition of hydrogen-bond competing agents (or 'denaturing agents'), such as urea or phenol, to the nucleic acid solutions produces an irreversible effect in which it appears that the nucleic acid, although unchanged in molecular weight by these agents, becomes more compact by a loosening of intramolecular hydrogen bonds which appear to stiffen the extended rod-like structure.

Both radiomimetic agents, for example, the nitrogen mustard



$$CH_3{-}N\begin{cases}CH_2.CH_2Cl\\ CH_2CH_2Cl\end{cases},$$

and X-rays have an apparent depolymerizing effect on nucleic acid. However, the chemical effects of these two types of agents are very different, and only the physical changes of viscosity and molecular weight are similar. In the case of the nitrogen mustard, direct alkylation of the nucleic acid alters the molecule to a more compact form. At the same time and afterwards, further fission of the nucleic acid chain occurs giving fragments of lower molecular weight. The chemistry of these processes was briefly discussed. In the case of the action of X-rays on aqueous solutions of nucleic acid, the reactive agents are the hydroxyl, hydrogen and hydroxylonium free radicals, the latter being formed only in oxygenated solutions. The chemical action of hydroxyl radicals on nucleic acid and simpler analogues was described. There is a wide variety of reactions which can be brought about by these hydroxyl radicals interacting with nucleic acid. The effects of X-irradiation of nucleic acid in oxygen are of particular interest, for here degradation continues long after cessation of the irradiation. The importance of hydrogen peroxide formed during the irradiation under these conditions was discussed, and the possible relation of the increased radiosensitivity of organisms in the presence of oxygen was pointed out. Dr. Conway's talk was beautifully illustrated by slides showing stages of cell division.

In the final paper, Dr. G. A. Gilbert (University of Birmingham) spoke of the work in the Birmingham laboratories and elsewhere on "Enzymes for Building Natural and Synthetic Starch". He said that natural starch contains two distinct kinds of polymer—a long straight-chain polymer (two hundred units) termed 'amylose', and a highly ramified polymer termed 'amylopectin'. Amylose tends to come out of solution in hot water in the form of a granular powder (retrogradation), whereas amylopectin forms a thick gel. Tough fibres resembling cellulose can be made from amylose. It gives a blue-coloured complex with iodine, the molecules and ions of which may fit inside a helix-type of chain structure. Amylopectin gives a reddish colour with iodine, and the amylose content of a starch may be measured by the 'blue value' of the iodine complex measured spectrophotometrically. Separation of amylose from a starch paste may be achieved by the addition of a variety of reagents, including thymol, paraffins, aluminium phosphate, etc.

Amylose may be synthesized by the action of an enzyme (Hanes's phosphorylase or *P*-enzyme) acting upon glucose-1-phosphate under appropriate conditions. The phosphorylase may be extracted readily from potato juice and obtained in a highly purified form. The synthesis using purified materials will not begin until a 'primer' consisting of several glucose units with the starch-type pattern is added. The synthesis starts from the non-reducing chain ends, and the glucose units are joined by 1 : 4 α-glycosidic linkages. Amylose may be converted into amylopectin by a second 'branching' enzyme termed *Q*-enzyme which has been obtained in Birmingham in a crystalline condition. The branching may involve 1 : 6-linkages which are now termed 'cross' linkages. The synthesis of the starch components by these enzymes, alone and in admixture in varying proportions, gives a valuable means of studying an important biological synthesis. The depolymerization of starch components can be studied by means of the 'amylase' enzymes, which have some commercial importance. There is a good deal of overlap in the mode of action of starch-synthesizing and -depolymerizing enzymes obtained from microbial, protozoal, plant and animal tissues.

The meeting concluded with a lively discussion.

OBITUARIES

Prof. C. B. Fawcett

PROF. C. B. FAWCETT, who held the chair of geography at University College, London, for twenty-one years until his retirement in 1949, died on September 21 at the age of sixty-nine.

A graduate of University College, Nottingham, he later studied under Herbertson at Oxford before becoming lecturer in geography at University College, Southampton, in 1914. He moved in 1919 to the University of Leeds, where he was in charge of the young Department of Geography until he was appointed in 1928 to succeed Prof. L. W. Lyde in London.

Fawcett was a leading member of the group of pupils of Mackinder and Herbertson who pioneered the modern development of honours schools of geography in British universities, and he was for many years prominent in the counsels of the Geographical Association, Section E (Geography) of the British Association, and the Institute of British Geographers, of which he was one of the founders and an early president.

A faith in the essential reasonableness of his fellow men, as well as his own rationalism, permeated all his work, and were revealed, for example, in his interest in the development of an auxiliary world language and calendar reform. They found particular expression in "The Bases of a World Commonwealth", published in the darkest period of the Second World War. His emphasis upon the unity of the Atlantic community combined with his personal qualities to make him a ready and welcome visitor to New England. Having already been visiting professor at Clark University, Worcester, Mass., in 1931 and again in 1947, he returned there for two years after retiring from the chair at University College, London.

It is perhaps too soon to attempt an assessment of his contribution to the development of geographical thought; but the significance of his early work, "The Provinces of England" (1919), in the history of the regional concept is already evident. That it should have been specifically written to point a reasonable basis for devolution of government and reform of administrative areas was typical of his essentially practical outlook. Geography claimed his absorbing interest not for its own sake, but also as a social science which in its application to social and political problems could increase the sum of human happiness. To the studies of population problems and political geography, which increasingly engaged his attention, he brought an insistence upon appreciating the realities of hard facts. His own command of facts was an unfailing source of wonder to his students, who will remember the encyclopædic knowledge on all manner of topics which illumined or diverted his lectures, as they will his unfailing kindliness and outstanding fairmindedness.

A. E. SMAILES

Prof. Aikitu Tanakadate

FRIENDS and acquaintances of Prof. Aikitu Tanakadate will learn with regret of his death on May 21 in Tokyo, after a long and active life of ninety-five years.

He was born in 1856 at Fukuoka town in the present Iwate Prefecture, Japan. Entering the University of Tokyo in 1878, he studied physics under J. A. Ewing and T. C. Mendenhall, and afterwards under C. G. Knott, who were at that time visiting teachers of the University. His interest was particularly directed towards geophysical phenomena, and soon after graduation he started gravimetric and magnetic surveys over Japan, which had not been explored scientifically by that time. "A Magnetic Survey of Japan", which was written by him with admirable thoroughness and completeness and was published in 1904, is universally known as a monumental work of this kind. In 1888 he went to Glasgow, where he studied physics as a pupil of Sir William Thomson (Lord Kelvin). He returned to Japan in 1891 and in that year was appointed a professor in the University of Tokyo, a post which he held until 1917.

Prof. Tanakadate was the oldest member of the Japan Academy of Science, an emeritus professor of the University of Tokyo, the first recipient of the Order of Cultural Merit, sometime vice-president of the National Research Council of Japan, and a member of the House of Peers. He also held important positions in many learned societies. For more than seventy years of his career as a scientist he literally devoted himself to initiating and promoting natural sciences in Japan. His activity covered fields in a wide range of subjects—to mention a few, geodesy, variation of latitude, seismology, terrestrial magnetism and aeronautics. Japan urgently needed such a pioneer as Prof. Tanakadate, particularly towards the end of the nineteenth century, after the Meiji Restoration of 1868, which brought to an end the three hundred years of Shogunate feudalism. His love of science as well as of his native country seems to have been the primary motive which drove him to this honourable duty. This does not mean that he was a man of narrow-sighted nationalism. On the contrary, he is known as a strong advocate of international friendship and co-operation. He travelled abroad no less than twenty-three times and attended a number of scientific assemblies and presided at several of them. He was the first president of the International Association of Terrestrial Magnetism and Atmospheric Electricity. C. E. Guillaume, of France, is said to have one day announced with mock seriousness that the second moon was newly born; his explanation to rather puzzled hearers was this: "It is Prof. Tanakadate. He makes a revolution around the world every year".

Prof. Tanakadate was liked by everybody who had the opportunity of becoming acquainted with him, and admired for his unfading love of science as well as for his logical and brilliant way of thinking, intermixed occasionally with a good sense of humour. Many old friends all over the world will honour his memory.

CHUJI TSUBOI

WE regret to announce the following deaths:

Dr. W. E. Gye, F.R.S., lately director of the Imperial Cancer Research Fund, on October 15, aged sixty-eight.

Sir Frederick Keeble, C.B.E., F.R.S., formerly Sheradian professor of botany in the University of Oxford, on October 19, aged eighty-two.

NEWS and VIEWS

Sir William Ramsay and University College, London

REFERENCE has already been made (see *Nature*, October 4, p. 554) to the appeal for funds which has been made on the occasion of the centenary of the birth of Sir William Ramsay. The appeal was well and truly launched at a Ramsay Memorial Dinner held at University College, London, on October 15, at which H.R.H. The Duke of Edinburgh was guest of honour and proposed the toast "to the immortal memory of Sir William Ramsay". He took as his theme the importance of fundamental research and its significance for industrial progress, quoting from his experience of recent work going on in State research institutions, and using Sir William Ramsay's discovery of the rare gases as an example of the manifold and unsuspected uses which may be made in everyday life and industry of the results of fundamental research. The reply to the toast was made by Dr. B. Ifor Evans, provost of University College, who outlined the purpose of the appeal, and stated that £57,000 has already been promised towards the £100,000 which it is hoped to raise. During the dinner, it was announced that Lady Tidy (a daughter of Sir William Ramsay) and Prof. Morris Travers—both of whom, with other associates of Ramsay, were present —had decided to present to the College the collection of Ramsay letters, papers and other materials which Prof. Travers has been accumulating over a long period. Incidentally, it may be added that Prof. Travers has prepared a fascinating account of Ramsay's life and work which has been issued by the College in connexion with the centenary appeal.

The appeal is being issued jointly by the University College Committee and the Ramsay Memorial Fellowships Trustees. After Ramsay's death in 1916, funds were raised by public subscription and were devoted partly to building a chemical engineering laboratory in the College and partly for the endowment of Ramsay Memorial General Fellowships to enable advanced students of chemistry from any part of the world to carry out research at any approved centre in the United Kingdom. Fellows from overseas are supported by funds raised in the country of their origin, and in this way Canada, Denmark, France, Greece, Holland, Italy, Japan, Norway, Spain, Sweden, Switzerland and the United States have sent distinguished young students to Great Britain. Funds subscribed in Britain were mainly devoted to British students, and the capital fund available for that purpose is now inadequate to maintain the normal award of one fellowship of two-years tenure every year. It is therefore proposed to devote £25,000 from the £100,000 which the appeal is hoped to produce to augment the Fellowship Trust General Fund, so that the normal number of British fellowships may be restored. With the remaining £75,000 it is hoped to make a substantial addition to the laboratory accommodation at University College and to provide additional equipment. When Ramsay went to the College, the facilities for research were meagre. By his personal exertions he supplemented what was available to him in the College, until he led a famous school of research. He would surely have approved the purpose of this centenary-appeal to industry and others to augment the resources of the College, so badly damaged during the Second World War, and to provide more funds for the maintenance of that world-fellowship of distinguished chemists who are proud to acknowledge their association with the Ramsay Memorial Trust.

The Royal Sanitary Institute: Dr. J. W. Dudley Robinson

AT a luncheon given in his honour on October 14, Dr. J. W. Dudley Robinson, who will be retiring at the end of this year, was presented with an inscribed silver rose-bowl and a cheque on behalf of the Fellows, Members and Associates of the Royal Sanitary Institute as a token of their appreciation of his valued service as secretary of the Institute since 1928. Dr. Robinson has also been secretary of the Royal Sanitary Institute and Sanitary Inspectors Examination Joint Board since 1928 and of the National Nursery Examination Board since its formation in 1945. Since he went to the Institute from the secretaryship of the Institution of Municipal Engineers, he has been responsible for much of the former's successful development. In addition to organizing the annual health congresses of the Royal Sanitary Institute, which are attended by upwards of two thousand delegates, he has also arranged a number of special conferences, notably on the Midwives Act in 1936, and on the administration of the Milk (Special Designations) Order in the same year. During his service with the Royal Sanitary Institute, Dr. Robinson has been responsible for its examination system under which some sixty-eight thousand candidates have been examined. In the same period, the membership of the Institute has increased from 4,700 to well over 9,500. In 1950 he was appointed an officer of the Ordre de la Santé Publique by the President of the French Republic.

New Fellowships in Microbiological Biochemistry at Oxford

THE University of Oxford has been able to establish three research fellowships in microbiological biochemistry in the Department of Biochemistry, owing to the generosity of Arthur Guinness, Son and Co., Ltd., who have offered to pay the University £2,500 a year for seven years for this purpose. The Guinness Research Fellows must be British subjects who are graduates of a university and who have had experience in research. They will be appointed by the Board of the Faculty of Biological Sciences in the University of Oxford, on the recommendation of the Whitley professor of biochemistry and the reader of microbiology in the Department of Biochemistry. It is anticipated that Fellows will hold their appointments for three years, receive a salary between £600 and £800 a year and carry out fundamental research in the field of the biochemistry of micro-organisms.

Centenary of the Royal Photographic Society

The Royal Photographic Society of Great Britain will be celebrating its centenary next year and will hold an international conference on the science and applications of photography in London during September 19–25, 1953. The conference will cover many aspects of the science, technique and applications of photography and will be divided into five sections dealing with the following topics: photographic science—including the theory of the latent image and development, sensitization, sensitometry, resolving power, granularity and the properties of photographic materials; cinematography and colour photography; technique and applications of photography—including industrial radiography, photomicrography, spectroscopy, aerial photography, photogrammetry, high-speed photography, nuclear track recording, and other physical, chemical and biological applications, as well as photocopying and photographic apparatus, processes and manipulations; photomechanical processes; history, literature—including abstracting and documentation—and training in photography. All persons taking an interest in photography or its applications are invited to attend the conference, and to submit papers for discussion. Titles and indications of the scope of such papers should be submitted before February 1, 1953, and the full paper before May 1, 1953; it is intended to publish the papers in full before the conference. All communications regarding the conference should be addressed to the Honorary Secretary, R.P.S. Centenary Conference, 16 Princes Gate, London, S.W.7.

Isotope School at Harwell: Course of Instruction

Since the opening in April 1951 of the Ministry of Supply's Isotope School at Harwell, a steady succession of courses has been held there in the technique of handling and using radioactive isotopes. So far, a hundred and fifty scientific workers, medical men and engineers have passed through the school, nearly three-quarters being from Great Britain, and of the remainder one-third being from South Africa, India and Australia and the other two-thirds from European countries. The students come in nearly equal numbers from five main groups: universities, technical colleges and research institutions; industrial research laboratories; industry; medical centres; and the Department of Scientific and Industrial Research and government departments. Nearly two-thirds of the total have been chemists and biochemists, and the remainder have been made up of engineers, physicists and medical men in roughly equal proportions. During the sixteen months of its existence the School has continually developed and attempted to have in its laboratories equipment which is abreast of the very latest developments all over the world. To house the additional equipment the School was moved from its original quarters, a converted wooden hut, and has, since January of this year, been installed in a permanent brick building where there are now ample facilities for carrying out all the physical and chemical manipulations required when working with radioisotopes. The courses last for four weeks, and in that time, by means of lectures and especially by working in the laboratory, a sound grounding in the principles of working with radioactive materials is given; the training is intended to be of a fundamental nature and does not deal with the very specialized techniques which have been developed for application in industry and medicine. The next courses in the School will begin in January 1953, and applications for admission and further information can be obtained from Dr. J. E. Johnston, Isotope School, A.E.R.E., Harwell.

Revival of Japanese Botany

Evidence that the vigorous interest in botanical science that was a feature of pre-war Japan is renewing itself is shown by the publication of "An Address Book of Japanese Botanists" (1951), edited by the National Committee of Botany, and published by the Science Council of Japan, Tokyo (no detailed address given). Some 350 names are given, with ages, addresses, qualifications, interests and publications, and the object is "to recover and further promote our scientific friendship with foreign botanists and relevant societies".

New Photoelectric Absorptiometer

The firm of Hilger and Watts, Ltd. (48 Addington Square, London, S.E.5), has recently started to produce a new photoelectric absorptiometer to be known as the 'New Biochem Absorptiometer'. It is a compact direct-reading instrument of the single-cell type designed for routine use in the laboratory. The controls comprise an on–off switch, a light control for setting the full scale reading, a shutter for the photocell, and a filter selector drum. The latter contains eight spectrum filters of narrow band-width. The photocell is connected to a sensitive reflecting galvanometer the white opaque screen of which enables readings to be taken more easily than with the usual semi-transparent type. Flat-sided cells or special test-tubes can be used, the mount for the latter being optically compensated for the refractive index of the solution. Spilt solutions merely drop through to the work bench; also the cell mounts are made of polythene. The instrument is either battery- or mains-operated with built-in constant-voltage transformer.

Inter-Library Microfilm Catalogue of the Scientific Libraries in Israel

A bi-lingual guide (in English and Hebrew) to the Inter-Library Microfilm Catalogue of the Scientific Libraries (Natural and Applied Sciences) in Israel has been issued by the Research Council of Israel, Jerusalem (pp. 100; 1952). The catalogue itself is the first part of a scheme to improve the scientific information services of Israel, and, for the present, copies are distributed only to the Research Council of Israel, Jerusalem, the Hebrew University (Terra Santa, Jerusalem), the Agricultural Research Station (Rehovot), the Bett Gordon Library (Dagania A), the Hebrew Institute of Technology (Haifa), and the

Engineers Institute (Tel Aviv). The guide indicates the scope of these libraries and the classification used in their several catalogues, so that application for the appropriate section of the microfilmed catalogue is facilitated. The present format and pagination of the guide are cumbersome and inconvenient to the user; the bi-lingual reports by, for example, the National Research Council of Canada or the South African Council for Scientific and Industrial Research are in a much better style.

Institute of Education Library, Birmingham

The Institute of Education Library, University of Birmingham, has issued a Supplement (No. 1, pp. 83; February 1951–March 1952) to the basic catalogue of 1951, mainly for the assistance of readers who cannot visit the Library. Items of less than 51 pages are indicated by the symbol [P]. The entries are classified under such heads as, for example, reference books (which cannot be borrowed), history of education, principles and philosophy of education, sociological aspects of education, national systems of education, universities and university education, adult education, vocational guidance, the curriculum, exceptional children, etc. A complete list of the Library's holdings of periodicals is included, and there is an author index.

Institute of Metals: New Officers

The following have been elected to fill vacancies on the Council of the Institute of Metals, with effect from the annual general meeting in 1953: *President*, Prof. F. C. Thompson (professor of metallurgy, University of Manchester); *Vice-Presidents*, Major C. J. P. Ball (chairman, Magnesium Elektron, Ltd.) and Prof. G. V. Raynor (professor of metal physics, University of Birmingham); *Members of Council*, W. A. Baker (research manager, British Non-Ferrous Metals Research Association), J. C. Colquhoun (chairman and managing director, Manganese Bronze and Brass Co., Ltd.), E. R. Gadd (chief metallurgist, Engine Division, Bristol Aeroplane Co., Ltd.) and the Hon. John Grimston (director and general manager, Enfield Rolling Mills, Ltd.). The Council of the Institute has elected Dr. S. F. Dorey (chief engineer surveyor, Lloyd's Register of Shipping) to serve as senior vice-president for the year 1953–54, and he will be nominated for the presidency for the year 1954–55.

Colonial Service: Recent Appointments

The following appointments in the Colonial Service have recently been announced: D. F. Davidson (assistant conservator of forests, Cyprus), senior assistant conservator of forests, Cyprus; J. K. Ross (assistant conservator of forests, Sierra Leone), assistant conservator of forests, Nigeria; J. M. Waterston (senior botanist, Nigeria), principal research officer, Agricultural Department, Nigeria; J. D. Birkett (senior veterinary officer, Nigeria), director of veterinary services, Sierra Leone; G. F. Darnell, agricultural officer, Federation of Malaya; G. E. Dixon, plant breeder, Kenya; P. Greening, agricultural officer, Northern Rhodesia; W. G. Plaistowe, agricultural officer, Nyasaland; R. M. Sister, entomologist, West African Cocoa Research Institute, Gold Coast; M. E. H. Vickers, agricultural officer, Kenya; P. E. Wheatley, agricultural entomologist, Kenya; R. C. Norris, chemist, Federation of Malaya; J. A. B. Stewart, geologist, Somaliland Protectorate; L. A. J. Williams, geologist, Kenya; A. D. McKelvie, plant physiologist, West African Cocoa Research Institute, Gold Coast; G. R. Robson, scientific officer, Trinidad (seismological observer in charge of recording station, Windward and Leeward Islands); D. J. Taylor, entomologist, West African Cocoa Research Institute, Gold Coast; R. Wilson, veterinary officer, Somaliland Protectorate; P. H. Gulliver, sociologist, Sociological Research Provincial Administration, Tanganyika; H. F. Lamprey, biologist, Game Department, Tanganyika; N. G. Shaw, assistant conservator of forests, North Borneo; R. Tavener-Smith, geologist, Northern Rhodesia; G. Webbe, entomologist, Medical Department, Tanganyika; E. Wigura, computer, Surveys and Town Planning Department, Tanganyika.

Announcements

Prof. M. von Laue, who will be addressing a meeting of the Physical Society at 5 p.m. on October 29 at the Science Museum, South Kensington, London, S.W.7, will first present the Max Planck Medal for 1952 to Prof. P. A. M. Dirac on behalf of the Association of German Physics Institutes.

Mr. N. D. Riley, keeper of entomology in the British Museum (Natural History), is relinquishing the editorship of *The Entomologist*, a post he has held for thirty-one years, and will be succeeded in the new year by Mr. D. Leston. The journal is to be increased in size and widened in scope to include all aspects of pure and applied entomology; all inquiries regarding it should be directed to the editor at 44 Abbey Road, London, N.W.8.

The National Science Foundation (2144 California Street, N.W., Washington 25, D.C.), in co-operation with the University of Chicago, is organizing a conference on the "Abundance of the Elements", to be held at the Yerkes Observatory, Williams Bay, Wisconsin, during November 6–8. The conference will bring together some forty leading astronomers, chemists, geochemists and physicists, drawn from university, industrial and government research organizations, who will consider the effect of recent research in stellar and terrestrial measurements on current theories of the abundance of elements in the universe. It is hoped that, as a result of this conference, fresh light will be brought to bear on the origin and material limits of the universe.

A fellowship and a number of scholarships for work on arctic or sub-arctic research are being offered jointly by McGill University and the Arctic Institute of North America, with the financial support of the Carnegie Corporation of New York. The fellowship, which is worth 4,000 dollars, is for a senior research worker who has completed his studies in the field and requires a year's residence in a centre of learning to prepare his results or acquire specialized knowledge. The scholarships are normally tenable for one year, being worth on the average 750 dollars with 1,500 dollars field expenses, and are for graduates intending to undertake active field research. Further information regarding these awards can be obtained from the Carnegie Arctic Program, Arctic Institute of North America, 3485 University Street, Montreal, P.Q. Applications must be sent in by January 1, 1953, except that scholarship candidates not intending to do field-work in the summer of 1953 need not send their applications until April 1, 1953.

EXHIBITION OF THE WORK OF W. STANLEY JEVONS

By DR. W. MAYS and DR. D. P. HENRY
Department of Philosophy, University, Manchester

IN *Nature* of January 27, 1870, Jevons's paper "On the Mechanical Performance of Inference" read before the Royal Society in the previous week was reported. The paper is a historic one, as it contains an account of the first logical machine. Built in 1869, this was used for teaching purposes while Jevons was at Owens College (now the University of Manchester) and in London. It was eventually deposited in the Museum of the History of Science, Oxford, and has been lent to the Philosophy Department at Manchester, which has arranged an exhibition in the Christie Library of the University (October 15–31).

The exhibition shows that the truth-table method of solving logical problems was introduced by Jevons in 1864. Indeed, without the use of this method he could not have constructed his logical machine. Mary Hesse, in her recent study of Boole's unpublished manuscripts (*Annals of Science*, March 1952), after speaking of Boole's attempt to arrive at a non-algebraic expression of his logical calculus, says (p. 79): "The suggestion was developed independently by Jevons, who solved Boole's general problem without the use of algebra by writing down all possible combinations of the terms. . . . The result is in the form of a truth-table from which any question regarding terms or combinations of terms can be answered. Jevons made this the basis of his logical machine. It is clear from the MSS. that although Boole was feeling after some such method, there is no real anticipation of Jevons in his work". Further light is thrown on this matter by a series of unpublished letters in the exhibition, containing an exchange of views between Boole and Jevons on the publication of the latter's "Pure Logic". Boole's letters confirm Miss Hesse's judgment that it is to Jevons that we owe the introduction of the tabular method which led to his mechanization of logic.

Allen Marquand (1853–1924), fellow in philosophy, Johns Hopkins University, and afterwards professor of archæology and the history of art at Princeton University, constructed an improved four-variable machine (*Proc. Amer. Acad. Arts and Sci.*, 1885). Letters of Marquand in the exhibition show his indebtedness to Jevons. Marquand's manuscripts, now in the Princeton University Library, were examined by Prof. Alonzo Church, the well-known logician, who selected the material on logical machines, photostats of which are included in the exhibition. There are details of an eight-term machine, a syllogistic variation machine, and notes showing the advantages of Marquand's machine over that of Jevons. A copy of Marquand's wiring diagram for a four-term electrical machine was also sent. Prof. Church thought it important for us to see it, as it was not mentioned in any of the published papers he could recall. The diagram is of great interest; prepared about 1885, it is probably the first circuit of an electrical logical machine. It is wired in series and parallel, and among its components are sixteen electromagnets, eight one-way switches, one three-way switch, and a rheostat. Jevons's principles thus received their electrical translation at least half a century before present developments in relay computing machines.

Exhibited together with Jevons's machine is the modern three-variable electrical relay computer built for the Philosophy Department of the University of Manchester by Messrs. Ferranti (see Mays and Prinz, *Nature*, 165, 197; 1950), based on similar logical principles. Jevons's machine to-day is as portrayed in the frontispiece of the "Principles of Science". It looks like a miniature upright piano; on both the front and back are slots through which can be seen the letters representing the sixteen possible combinations of the four terms *A*, *B*, *C* and *D*, and their negations, thereby constituting a truth-table. It has a keyboard with twenty-one keys for terms and operations, by means of which the machine rods which bear these combinations can be classified, selected or rejected. The machine can deal with 65,536 possible logical selections. As the original report in *Nature* in 1870 says: "When once a series of propositions is thus impressed upon the machine, it is capable of exhibiting an answer to any question which may be put to it concerning the possible combinations which form any class. The machine thus embodies almost all the powers of Boole's logical system up to problems involving four distinct terms . . . demonstrating in the simplest and most evident manner the character and powers of a universal system of logical deduction, of which the first, although obscure solution, was given by Dr. Boole."

Jevons's logical notebooks are also exhibited. In one of them he works out all the 256 possible logical selections generated by three terms. They are displayed in the form of four panels drawn on graph paper. The notation is a binary one: dots indicate the existence of a combination, spaces their absence. In the "Principles of Science" (2nd edit., p. 135) and in some of his notebooks, he uses the 1 and 0 notation which has become so familiar to-day in logical and mathematical computers.

The exhibition also includes the manuscripts of many of Jevons's writings on economics and logic, and copies of his published works. Of direct interest to the economist are coloured charts of great complexity prepared for his "Statistical Atlas". There are letters from Gladstone, Bagehot, J. S. Mill, H. Spencer, Galton, Babbage, Venn, C. S. Peirce and many documents of economic interest. Notes on his experiments on Brownian motion (1878) further illustrate the variety of his interests. His journal during 1853–67, parts of which have appeared in the "Letters and Journal" edited by his wife, is also to be seen, as well as his drafts of class reports at Owens College, his memorandum books, personal reference books, photographs taken during his stay in Australia and family and University photographs.

W. Stanley Jevons was born in Liverpool in 1835, and died at the early age of forty-seven in 1882. He was professor of logic, mental and moral philosophy, and Cobden professor of political economy in Owens College (1866–76), and professor of political economy in University College, London (1876–80). To Jevons are due many important innovations in economics and logic; these, together with his researches in numerous other fields, reflect his versatility and brilliance.

The exhibition of the Jevons manuscripts and correspondence has been made possible by the kindness of his son and daughter, Mr. H. S. Jevons and Miss H. W. Jevons. Mrs. Eleanor Marquand Delanoy gave permission for the use of her father's manuscripts, and Dr. Tyson, librarian of the University of Manchester, allowed the use of the Christie Library for the exhibition.

TRANSPORT IN GREAT BRITAIN

IN a paper on "The Troubles of Transport", read on September 9 to Section F (Economics) of the British Association at the recent meeting in Belfast, Prof. C. F. Carter (professor of applied economics in Queen's University, Belfast) discussed some current problems of road and rail transport in Great Britain. Figures were quoted showing that transport is an expanding activity (thus making adjustment easier); that it is mostly by road; and that 45 per cent of the 'activity' of transport is organized as an ancillary to some other activity. "It is most unlikely," said Prof. Carter, "that the ownership of ancillary vehicles would have developed to this point if it were not an efficient way of organizing transport. There is . . . no evidence that it would be advantageous to break it down. It follows that the possible field for public ownership of the carriage of goods by road is only a minor part of that activity."

The discussion of transport problems in the past year, continued Prof. Carter, has been concentrated on organization and ownership, and has avoided the fundamental issues, which are the relation of charges to costs, the problem of public obligation, and the principles of taxation of road transport.

In theory, the charge for an item of transport should be proportional to the cost of providing an extra unit flow of transport service of that type, when the system has been fully adapted to supply the extra services effectively and conveniently. The ratio of two charges should equal the ratio of costs, taking no account of interest on the cost of 'permanent' assets such as the road bed. The difficulty of costing transport services is very great, and the results must be in part arbitrary. With the railways, enough is known to show that "the present pattern of charges not only bears no relation to costs, but often works the other way". On the road, the difficulty is to find a true economic cost when taxation is so important. Prof. Carter pointed out that "the 'cost' of the roads should for our purposes mean the cost of maintaining and improving them so that next year they can carry traffic as speedily and safely as this year"; with road vehicles increasing in number by 5 per cent per year, this cost would much exceed the sums at present being spent on maintenance. A National Roads Council is needed, charged with the duty of advising on road development and of keeping running estimates for five years ahead of the least expenditure necessary to maintain the roads and to adapt them to expected traffic requirements. Part of the taxation of road vehicles should be segregated as a Roads Tax, paid into a revived Road Fund, which would be autonomous and would carry forward balances from year to year. The Fund should receive what the National Roads Council estimates to be the proper sum to be spent on the roads—whether or not the economic situation allows this amount to be actually spent.

"A more fearsome dragon now lies in our path, called the Public, who are supposed to insist on various uniformities which flatly contradict the principles we have been discussing." Thus rail passenger fares are expected to be proportional to distance, whereas they should be tapered. Uniformity of rates over the whole of a public organization's system prevents any reflexion of the large differences in cost between different routes. Proposals for dealing with this on the railways were made in Prof. Carter's paper.

After traders have chosen to carry what is convenient to them in their own vehicles, and road hauliers have given preference to profitable traffic, the common carrier by road or rail is left with the odd lots, the awkward cross-country journeys; in particular, the railways are left with precisely the traffics which economically they are least fitted to handle. "If we reject any solution to this problem which involves forcing users to use a particular kind of transport, there seems to me to be only one solution: substantial differential taxation of those parts of transport which have the privilege of choosing their traffic."

The proper taxation of road transport thus has four parts: the general requirements of the Chancellor of the Exchequer; a tax on petroleum, as long as the state of the balance of payments is deemed more grave than the coal supply; a roads tax; and a levy on those not accepting public obligations.

Towards the end of his paper, Prof. Carter remarked: "I think we need a cooling-off period, to help transport to recover its commercial commonsense after a surfeit of politics; and the best cooler would undoubtedly be a weighty Royal Commission, charged with the duty of giving the whole matter up-to-date and careful study".

SHAPES OF AEROPLANE WINGS

A PAPER on "The Shape of Wings to Come", by Mr. D. Keith-Lucas, chief designer of Short Bros. and Harland, Ltd., was read on September 8 before Section G (Engineering) of the British Association at the recent meeting in Belfast. The paper has since been published in full in *Engineering* (174, 349; 1952). It is of considerable interest as it goes a long way towards explaining the departures from orthodoxy of wing form which can be seen daily by persons who live near certain airfields.

Mr. Keith-Lucas explains that the main purpose of sweep-back is the reduction and the postponement to higher speeds of compressibility effects normally met with on straight wings at high subsonic speeds. The velocity of the wing relative to the air may be resolved into components normal to and parallel to the span. It is shown that the main aerodynamic effects are fixed by the former, so that the effective air speed of the wing can be made low by the use of sweep. End effects, at the root and the tips of the wing, reduce this benefit by half. It is also shown that at high supersonic speeds the unswept wing can be made efficient again, providing only that it is very thin; for example, the thickness of the sections may have to be as little as 3 per cent of the chord. Sweep-back was first introduced, however, in order to stabilize the all-wing aeroplanes which it was hoped to use before the penalty of severe drag of the resulting thick wing was fully appreciated. There is an interesting discussion in the paper of an Australian project for an all-wing airliner using a 30 per cent thick wing fitted with boundary-layer suction in order to reduce the drag.

The thin swept-back wing is shown to be peculiarly susceptible to aeroelastic effects; that is, to the aerodynamic consequences of structural distortion in flight. A simple example of such an effect is the so-called aileron reversal. This is also met in unswept wings. If the extra lift produced by the downward deflexion of an aileron acts towards the rear of the wing, it produces a 'nose down' twist of the structure which will cause a net loss of lift at sufficiently high speeds. An academically interesting solution to the general problem is the 'aeroisoclinic' wing invented by G. T. R. Hill. This leads to a swept wing which is weak in torsion. Aileron reversal is to be avoided by obtaining lateral control from wing tips the incidence of which to the wind can be varied, instead of the conventional ailerons. The case for crescent wings is also made. It seems, however, that at moderate supersonic speeds there is little to beat the delta planform with its large internal volume, especially at the wing root. This allows ample space for a stiff structure, the load, the fuel, the undercarriage, and the whole variety of apparatus and equipment carried by modern aeroplanes.

It is a big problem to get highly swept wings to give adequate lift at slow speeds, and the possible solutions of the landing problem are the subject of controversy among aeronautical scientists and engineers. An American aeroplane with sweep which is variable in flight has recently been flown. There are advocates of the use of parachutes, stowed helicopter blades, etc. In fact, the shape of wings to come is as yet indeterminate because of the difficulties of flying slowly.

HARNESSING KNOWLEDGE

ANNUAL CONFERENCE OF ASLIB

THE fact that Aslib could choose "The Significance of Information in Present-Day Industrial Society" as the theme of its twenty-seventh annual conference, held recently at Swanwick in Derbyshire, clearly indicates that the day is past when 'information' could be dismissed as the concern of the chemist or physicist alone. The very phrase has an Aristotelian ring that nevertheless yields nothing in emphasis to the twentieth century's pre-occupations with men as minders of machines. So, indeed, it should be, for as Sir Stephen Tallents declared in opening the conference, "ideas have to-day become not only the most potent of forces but also the most precious of cargoes". Those same ideas, communicated and applied, are the life stream of an industrialized society, which must perish unless it can produce more goods more cheaply than ever before.

In this modern industrial and scientific society, the key to future development is the speed with which new ideas can be put to work—such was the burden of the principal paper at the conference, presented by Prof. T. U. Matthew, who holds the chair of engineering production in the University of Birmingham—the only one of its kind in Great Britain. We have, he said, achieved a new type of chain-reaction in which new knowledge and ideas, travelling at a rate governed by the effectiveness of our information services and means of publication and communication, give rise to an endless succession of transmutations and further ideas in an ever-widening range of specialized fields of research and development. For the truth of this, one need not look beyond the post-war capital development programmes in coal, steel and chemical production, which have all felt the impact of modern methods of communication on a large scale.

These, it is true, are fields in which, for the most part, large industrial units are engaged. It is encouraging to know that, according to the recent survey "Research and Development in British Industry", produced by the Federation of British Industries, some £30,000,000 is now being spent on research each year compared with £5,500,000 just before the Second World War. But responsibility for bringing into the production stage the vast stores of new knowledge that become available in this way still lies generally with a comparatively small group of larger companies. Behind them stretch the thousands of firms of intermediate and smaller size, the majority of which have not, as yet, got to grips with the concept of increasing productivity, let alone the definitive shape that can be given to that concept by the utilization of published facts and figures. Add to this picture of the production side of industry the stimulus that can come from the communication of data and ideas in connexion with home and foreign markets, internal and external freight facilities, international trade and currency regulations and, not least, industrial labour relations—the vision is stirring indeed.

Here, as Prof. Matthew indicated, arise both the immediate obstacle and the long-term challenge. It is already clear, he said, that the present rate of discovery arising from fundamental research in physics, chemistry and the applied sciences, far exceeds the digestive capacity of existing development resources—hence the growing pressure for a new technological university and more technologists to bridge the gap between scientific research and industrial application. On a wider stage, the rate of exploration of the world's raw material resources has outstripped the nations' capacity to finance and organize their development. To this fact can be traced such schemes as the United Nations technical assistance projects, the 'Point 4' plan of the U.S. Government and the Colombo plan. Both nationally and internationally, these far-sighted proposals mean a mounting pressure on information services. Steps to encourage the interchange of knowledge and to speed up the processes of accumulating, abstracting, classifying and disseminating information on research and technical developments, production processes, raw material resources and market opportunities have already been taken, nationally, by Aslib, the Department of Scientific and Industrial Research and the research associations and, internationally, by the Office for European Economic Co-operation and the British Commonwealth Scientific Offices. The danger is that, in the smaller firms which have not yet established information departments of their own, these existing facilities may pass unnoticed, at least until the supply of technologists has increased. For the immediate future, he said, it is a question of assisting individual managers, who are not yet alive to the great wealth of recorded information open to them, to exploit it with only their present resources of staff. To Henri Fayol's six activities of management of fifty years ago, it is now time to add a seventh—the information function; and on the performance of it in the next decade or so the long-term future of British industry may well depend.

If, indeed, information services are destined to play such a crucial part in the future of British industry, much of the credit for an early realization of their potential value must go to the Royal Society's Information Services Committee and to Aslib, the work of both of which since 1948 was reviewed in papers presented by Dr. D. J. Urquhart and Mr. Leslie Wilson. The story of their achievement in barely four years is, perhaps, one of the most creditable on the less sensational side of British recovery since the War. Yet there can be no room for complacency while it can be said, as Dr. Urquhart did, that "there do not appear to be any major faults in the system [that is, of information services] as significant as the fact that so many who might use the system more, hardly use it at all". A recent survey indicated that 75 per cent of all industrial organizations have less than five periodicals of any sort and less than fifty books. At the same time, it has never been clearly demonstrated that the kind and size of firms that one might reasonably expect to find among the 75 per cent could and should be able to make use of published information on a scale likely to affect turnover materially. The firms themselves are mostly inarticulate or unaware of their need of information, technical or otherwise. The next step is surely to reduce this diffuse problem to measurable proportions, to ascertain at what level information services should operate in order to make the greatest contribution to the numerous and varied groups of potential information users. This is research of a kind in which, it is to be hoped, Aslib may be enabled to give an early lead.

MINERAL DRESSING

SYMPOSIUM IN LONDON

AT the beginning of this century the extraction of valuable minerals from their host rocks and ore complexes was a craft rather than a science. With the mounting demand, first for more and more engineering metals, and later for alkali earths and the oxidized earths of the rarer metals, it became necessary to exploit low-grade ore-bodies hitherto considered uneconomical. Two World Wars accelerated industrial demand, and at the same time forced the crude processes of those days on to a more scientific basis. It is a far cry from the 'préparation mécanique' and the 'ore dressing' of the past generation to the precise process engineering of the modern mineral-dressing plant. A satisfactory title for the wide range of activities embraced by this phrase 'mineral dressing' remains to be found. Treatment starts with the reduction of large pieces of rock to an average particle size of anywhere down to a few microns, and then uses such forces as gravity (simple or reinforced by centrifugal acceleration), magnetism and electrostatic deflexion, and, above all, the differences between the surface tension effects on minute particles in order to render them amenable to the froth flotation process and allied techniques. The field of application in industry is constantly being enlarged by the fundamental technological research work now actively in process in a number of laboratories. This again is reflected in the increasing exploitation of ore deposits hitherto considered too low in grade to be worth treating. Industrial specialization has moved mineral dressing into the position where it takes over practically everything produced underground or in open-cast work and rejects suitable quantities of valueless material, while bringing up the balance to a closely controlled specification which aims at optimum technical preparation for subsequent processes such as smelting or leaching, the production of a variety of finished substances (for example, asbestos) or the purification of such earths as phosphates to the point where wet chemical processes can best be applied to the upgraded concentrates.

Evidence of the wide scope of these technical developments was supplied by the first symposium on mineral dressing ever to take place in Great Britain, which was held during September 23–25 under the auspices of the Institution of Mining and Metallurgy at the Imperial College of Science and Technology, London, an inaugural lecture (the Sir Julius Wernher Memorial Lecture) being delivered at the Royal Institution the previous afternoon by Prof. A. M. Gaudin (see *Nature*, October 18, p. 656). Thirty-nine papers were presented, covering the international field of research and application. Size, surface area, shape and lattice structure were brought together in a series of papers which dealt with discontinuity lattices and their effects on minerals chemically almost identical. The mathematics of crushing and grinding are at present statistical rather than fundamental, and are showing that the hypotheses of Kick and Rittinger, which during the past century have aged unobtrusively into 'laws', are not entirely satisfactory. Papers on comminution and precise measurement of products down to the 5-μ range discussed the role of stresses shown at the surface of the particle as 'crack tips', and defined and described the principles and laboratory techniques now available for the measurement of sizes and surface areas of the crushed products. Sub-sieve methods using sedimentation and elutriation in gaseous and liquid columns were compared. The practical aspects of this work in its extension to process control were covered in another group of papers. One important aspect of this branch of technical research is its use in the reduction of huge tonnages of low-grade ore to a closely controlled size-range of particles having a suitably differentiated condition at their individual surfaces as a prelude to separation by froth flotation, a process which can operate in suitable cases with high efficiency on particles as small as 3 or 4 μ in diameter.

The limitation of 'heavy media separation', as the process is industrially called, has been progressively reduced until to-day suitable material down to 20 mesh (Tyler) can be treated, although such a small size is exceptional. In one of the papers describing plant operation, a daily tonnage of 12,800 was mentioned, treating diamondiferous 'blue clays' down to 10 mesh by this method. The operating characteristics of the hydro-cyclone received new elucidation in two papers. This instrument applies controlled centrifugal force to a moving stream of particles and aids them to segregate in accordance with their difference of mass. Provided there is a marked difference of density in the + 100-mesh field, simple gravitational force can be used for this work; but as the Newtonian laws of settlement give place to Stokesian sedimentation, accelerated gravitational fields must be used if large quantities are to be handled quickly. The fundamental work of the Dutch and British laboratories in this intricate research is important. Two papers reported developments in the use of air as a commercial separating medium in desert country.

The largest group dealt with the froth flotation process, at all levels from that of the fundamental worker in surface chemistry to that of the specific problems handled in exploiting plants. The physics of frothing, aeration and attachment of a hydrophobic particle to an air-bubble in water were well represented. The effects of minute traces of soluble ions on the specific development of hydrophilic and hydrophobic surfaces were also considered. Other papers dealt with ion-migration study involving radioactive isotopes and the application of electrochemical methods to flotation research.

The present position of magnetic, electrostatic and photometric techniques was discussed in three papers. A striking symptom of change is the fact that only one paper dealt with the chemistry of cyanidation, although two others discussed plant practice in gold extraction. If mineral dressing had been of sufficient importance twenty years ago to bring together an international gathering of this calibre, the cyanide process might have dominated the scene. Even on the Rand, where the technology was first established, the main interest is now in the flotation of uranium from cyanide tailings—a process still on the secret list and therefore not presented at this symposium. Among the papers dealing with commercial practice was one on lead–zinc concentration, one on a gold–copper–zinc–pyrite complex, one on the design of small plants and one on the milling of asbestos.

The symposium brought a large gathering of scientific workers and engineers from all over the world, and discussion and interchange of views were sustained at a high level throughout the three days of the meeting. Appropriately to the occasion which had brought so distinguished a gathering of experts to Britain, the partly completed sections of the reconstructed Bessemer Laboratory of the Royal School of Mines were open. The 1910 layout, which contained what may have been the earliest pilot plant for industrial teaching and research, is being modernized to meet the need for specialized training of students and to provide further facilities in Britain for research in ore concentration, one development of which is the new degree course of the University of London in mineral dressing. E. J. Pryor

NEW RESEARCH TECHNIQUES IN PHYSICS

SYMPOSIUM IN BRAZIL

A SYMPOSIUM on "New Research Techniques in Physics" was jointly organized by the Academia Brasileira de Ciencias and the Centro de Cooperación Científica para América Latina (Unesco) and was held in Rio de Janeiro during July 15–22 and in São Paulo during July 24–29. The meeting had a double purpose: to provide for Latin American physicists an opportunity of discussing their problems, as part of a more general programme of the activity of Unesco in Latin America, and to stimulate and help the development of modern research in Brazil, by inviting a number of distinguished foreign scientific workers. The meeting was sponsored by the Conselho Nacional de Pesquisas (National Research Council; president, Admiral Alvaro Alberto), and, in São Paulo, by the University of São Paulo.

The number of foreign participants was very encouraging, and Latin American physicists came from Argentina, Bolivia and Mexico, of whom the strongest group was that from Mexico, giving seven papers out of a total of sixty-seven. Prof. M. S. Vallarta (Mexico) reported on an injection mechanism of charged particles due to the variable magnetic field of sunspots. He pointed out that protons in a sunspot could be accelerated up to 6×10^{9} eV.; while electrons, in the same field, would lose most of their energy by electromagnetic radiation.

I. Escobar (Bolivia) reported on work he had done at Echo Lake on the east–west asymmetry of positive and negative mesons. He expects to be able very soon to continue this work on the geomagnetic equator, at the high-altitude station at Chacaltaya (5,300 m.) which will be operated jointly by the Universidad Mayor de San Andrés (La Paz) and by Dr. C. Lattes, Centro Brasileiro de Pesquisas Físicas. Two papers were read by Argentine physicists: K. Fränz has constructed in Buenos Aires an electronic multiplier, which gives 1,000 multiplications per second with a precision of about ·1 per cent, and R. Gans showed how he has been able to solve Hallén's integral equation for the current in a linear antenna in the neighbourhood of resonance frequencies, obtaining a remarkable agreement with experiments.

Prof. J. Costa Ribeiro (University of Brazil) gave a detailed report on a new phenomenon which he has called the thermodielectric effect. He has found that the transition of many dielectric substances from the solid to the liquid state is accompanied by a weak electric current. In the case of naphthalene, the effect is of the order of one electron charge liberated for 10^{19} molecules passing from one phase to the other. Prof. Ribeiro pointed out that the detailed mechanism of the phenomenon is, however, not clear and that it has not yet been possible to establish to what degree the effect is characteristic of a pure substance and how it becomes, eventually, influenced by adding foreign ions.

Several papers dealt with work in Prof. B. Gross's laboratory at the Instituto Nacional de Tecnología. Prof. Gross reported briefly on the behaviour of an electret under variation of temperature and, in another communication, dealt with the work which leads him, alternately, to consider the transformations which connect creep and relaxation of elastic substances and admittance and impedance of electric circuits. He also dealt with electric networks connected either in parallel or series. H. Barbosa (University of São Paulo) reported on certain semiconductors which he has found to be very sensitive to elastic deformations. Prof. R. M. Fuoss (Yale University), who spoke in Portuguese, gave an account of work on polyelectrolytes, in which large polymer molecules carry several charged atoms. Chain molecules are known to influence the viscosity of a solution and, in the case of polyelectrolytes, electrostatic forces, which modify this influence, have to be considered.

A considerable fraction of the symposium was devoted to new apparatus. In the inaugural session H. L. Anderson reported on the new 170-in. synchrocyclotron at Chicago, and D. W. Kerst (University of Illinois) described the three betatrons which are now in operation in Urbana, reaching X-ray energies of 22, 80 and 320 MeV. M. D. Sousa Santos (University of São Paulo) reported on the betatron which he has put into operation in São Paulo and which furnishes X-rays up to 29 MeV.; it is the first instrument of that power which has been set up in Latin America. A series of communications of his collaborators dealt with results which have been obtained so far with the São Paulo betatron, using the excitation function of ^{63}Cu (γ,n) ^{62}Cu in order to test the energy spectrum and the angular distribution of the X-ray beam.

R. G. Herb (University of Wisconsin), F. Alba (University of Mexico) and O. Sala (University of São Paulo) discussed electrostatic generators. In Mexico a 2-MeV. Van de Graaff generator, made in the United States, has been put into operation, while the São Paulo generator, designed to give 3·5 MeV., is still under construction. J. Marshall (University of Chicago) described his Čerenkov counter for cosmic rays, and this was followed by a number of papers dealing with experimental observations noted during the construction of Geiger–Muller counters. S. de Benedetti (Carnegie Institute of Technology) described a coincidence circuit which, in connexion with scintillation counters, permits him to obtain a time resolution of 10^{-9} sec., sufficient to determine the time of flight of a gamma-ray quantum over a distance of a few centimetres. P. Ribeiro de Arruda (University of São Paulo) showed a diffusion cloud chamber operating at a constant temperature gradient.

G. P. S. Occhialini (Brussels) replaced his report on nuclear emulsions by a more detailed seminar in that field. The results which were communicated at the symposium showed clearly four different lines along which modern physics is progressing, namely, modern quantum electrodynamics, nuclear forces, mesons and high-energy phenomena.

Dealing with the first of these, though modern quantum electrodynamics was not represented at the meeting, it intervened in the report of M. Deutsch (Massachusetts Institute of Technology) on positronium. The transfer of momentum between an electron and positron by means of virtual annihilation was studied many years ago by Bhabha, and its influence on the hyperfine structure of the electron–positron system has been discussed by J. Pirenne. But when Dr. Deutsch recently succeeded in determining this hyperfine structure by registering the annihilation radiation of positronium-levels, he not only verified directly the existence of these forces, but he was also able to measure the radiative corrections for them. Dr. de Benedetti has been able to measure the life-time of positrons in metals and has found the surprising result that this life-time does not depend on the particular metal used. He has also been able to register three photon disintegrations of positrons, a phenomenon which, in agreement with theory, is about 370 times less frequent than two photons disintegrating. We can already expect that a new chemistry will be found, one in which hydrogen becomes substituted by positronium, though the substances to be studied will have an extremely short life-time.

Nuclear forces were dealt with in Prof. E. P. Wigner's report. Recent work in Princeton University has led him to the conclusion that the strong spin-orbit coupling, characteristic for the nuclear shell model, can be understood, at least by sign and order of magnitude, as a result of the action of central and tensor forces. A similar result has been found by R. Oehme (Instituto de Física Teórica, São Paulo), who considered the motion of a nucleon in the pseudoscalar meson field of a core. Prof. Herb described the precautions he has had to take in order to make sure that at 4·2 MeV. a small amount of proton scattering appears in the proton–proton collision. Prof. Kerst mentioned in his report the possibility of studying the photodisintegration of deuterons in the energy-range 150–300 MeV.

Important progress has been made in the study of the meson field. A target, beryllium, aluminium or liquid hydrogen, placed in the proton beam of the Chicago synchrocyclotron, has been instrumental in obtaining π-mesons from proton–proton collisions up to 220 MeV. Both Dr. Anderson and Mrs. L. W. Marshall reported on work done with meson beams. Cross-sections were determined for the processes:

$$\begin{aligned} &\pi^+ + p \rightarrow \pi^+ + p, \\ &\pi^- + p \rightarrow \pi^0 + n, \\ \text{and } &\pi^- + p \rightarrow \pi^- + p. \end{aligned}$$

Comparison between these cross-sections was possible at 135 MeV. The elastic scattering was found to be about isotropic, while the charge exchange leads to a marked backward scattering. The cross-section of the first process has been found to be several times larger than that of the last. The observed values agree well with a charge-symmetric interaction which makes the total isotopic spin an integral of motion.

Prof. Kerst's large betatron gives photoproduction of π-mesons, a subject which is under investigation. A search has been made to detect V-particles, so far without result; there is certainly less than one V-particle per 2,500 photomesons at 300 MeV. The difficulties of meson theory were emphasized by J. Leite Lopes (Centro Brasileiro de Pesquisas Físicas), who reported on an attempt made by himself and R. P. Feynmann with the aim of accounting for the deuteron structure by means of pseudoscalar mesons. An interesting point was brought forward by G. Fialho (Centro Brasileiro de Pesquisas Físicas), who, following the suggestion of Prof. G. Tiomno, showed that the, eventually anomalous, magnetic moment of the μ-meson accounts for most of the weak γ-radiation which accompanies the $\pi \rightarrow \mu$ decay.

Finally, high-energy phenomena, in particular the multiple production of mesons, were discussed in two papers. G. Molière (Centro Brasileiro de Pesquisas Físicas) reported on work he had done in Göttingen together with J. Budini—a phenomenological theory of the development of a nucleon cascade. G. Wataghin (University of Turin), outlining what has grown out of the pioneering work he had done during fifteen years in São Paulo, discussed a field theory with non-localized interaction, which promises to account for multiple meson production.

It is perhaps surprising that no new meson was reported during the symposium, though almost a month had passed since a previous meeting of nuclear physicists in Copenhagen.

Among the many other interesting papers, mention must be made of a report by Dr. D. Bohm (University of São Paulo) on his attempt to give a causal interpretation to the formalism of quantum mechanics.

The symposium was judged by all concerned to have been very successful, and not the least credit for this is due to Dr. A. Moses, president of the Brazilian Academy, and to Prof. J. Leite Lopes, who devoted several months to the work of organizing it.

EXPERIMENTS ON THE USE OF DDT, BHC AND DIELDRIN AGAINST ADULT MOSQUITOES AT TAVETA, KENYA

By G. DAVIDSON
Ross Institute,
London School of Hygiene and Tropical Medicine

DURING the past two years, simple mud-walled, thatch-roofed huts fitted with exit window traps and occupied by volunteer Africans have been sprayed with various formulations of the three insecticides, DDT, BHC and dieldrin, and the effect on the *Anopheles gambiae*, *A. funestus* and culicine mosquitoes entering them observed. Daily mortalities among the mosquitoes were determined by counting the dead individuals on the floors of the huts, and counting those dying later (within 12 hr. of capture) which were caught alive inside the huts in the morning and in the window traps during the night.

In these huts, before any insecticide was applied, it was found that most of the female *A. gambiae* and *A. funestus*, which entered during the night to feed on the occupants, rested inside the huts after feeding until their blood was digested and their ovaries matured. The gravid mosquitoes then left the hut in the evening. Except during the season of peak production of these species, more mosquitoes left the huts in the evening than during the rest of the night. Nearly all those leaving during the rest of the night and early morning were unfed individuals; very few were fed and showing ovarian development.

In the first series of experiments, an attempt was made to repeat the observations made by Muirhead Thomson[1] in similar huts in Tanganyika. This author, using the DDT wettable powder 'Ditrene', at an estimated dosage of 400 mgm. DDT per square foot, and the BHC wettable powder 'P.530', at 200 mgm. BHC per square foot (26 mgm. of the gamma isomer), concluded that DDT applied to the internal surfaces of a hut only irritated resting *A. gambiae* and *A. funestus*, causing them to leave the huts without actually killing them. BHC, on the other hand, proved a most efficient residual insecticide and, during the period of his observations (up to thirteen weeks after spraying), no mosquitoes were observed to escape its killing action.

In these experiments, where the insecticide dosages were chemically estimated at 98 mgm. DDT per square foot for 'Ditrene' and 153 mgm. BHC (20 mgm. of the gamma isomer) per square foot for 'P.530', the almost complete absence of kill with 'Ditrene', recorded by Muirhead Thomson[1], was not confirmed, even with the much lower dosage employed. The overall mortality among female *A. gambiae* and *A. funestus* in the 'Ditrene'-treated hut was 40 per cent in the first month after treatment, falling to approximately 20 per cent in the following two months. The results did show, however, that a large proportion of the mosquitoes escaped the action of this insecticide. In the hut treated with BHC, the mortalities in the first three months were much higher, namely, 99 per cent, 95 per cent and 60 per cent respectively.

Later experiments, using other formulations of DDT and BHC, confirmed these findings. In all the huts treated with DDT, a significant proportion of the female *A. gambiae* and *A. funestus* entering them escaped unharmed, even immediately after treatment. This proportion was always more than 20 per cent, but never as high as in the hut treated with 'Ditrene'. The DDT formulations and their chemically estimated dosages used in these later experiments are shown in Table 1.

TABLE 1

Formulation	Dosage (in mgm. DDT per sq. ft.)
Suspension of crystals, 0–30 microns	124
Suspension of crystals, 30–70 microns	51
'Murphy Paste'	238
'Murphy Wettable Powder'	229

For six months after treatments with these DDT preparations, the overall mortalities among female *A. gambiae* and *A. funestus* remained, for the most part, between 50 and 70 per cent, and even in the seventh to ninth months, between 40 and 60 per cent.

The suspension of smaller crystals produced higher kills in the first two months after treatment than did that of larger crystals, confirming the laboratory findings of Hadaway and Barlow[2]. The relatively poor kill produced by the 'Ditrene' in the first series of experiments is accounted for by the fact that this preparation contains a high proportion of large DDT crystals of the order of 80 microns.

The marked irritant properties of DDT were indicated by the fact that the majority of the mosquitoes were caught leaving the huts treated with DDT during the night and early morning, that is, in the window traps, and many of these were freshly blooded individuals. The proportions found dead on the floors of these huts were relatively small.

Two huts treated with BHC—the wettable powder 'P.520'—at 21 mgm. of the gamma isomer per square foot, and the oil-bound suspension 'Supona B' (TP.725), at 18 mgm. of the gamma isomer per square foot, produced similar results. In the first month after treatment, no female *A. gambiae* and *A. funestus* escaped the effect of these preparations. In the second and third months the overall mortalities among these two species fell from about 90 to 70 per cent, and in the fourth to sixth months from 50 to 30 per cent. In these huts treated with BHC, in the first four months after treatment a higher proportion of the mosquitoes were found dead inside the huts and a lower proportion in the window traps than occurred in huts treated with DDT.

A hut treated with a mixture of BHC and DDT in an oil-bound suspension (TP.726) at calculated dosages of 54 mgm. BHC (7 mgm. of the gamma isomer) and 223 mgm. DDT per square foot, showed the high initial kill of BHC (94 and 88 per cent overall mortalities among female *A. gambiae* and *A. funestus* in the first two months after treatment) and the moderately high, long-lasting kill of DDT (76, 63, 82 and 59 per cent in months three to six). The irritant effect of DDT was again indicated by the high proportion of the mosquitoes collected from the window traps.

In the later experiments a hut was also treated with the new insecticide, dieldrin. This was applied in the form of a wettable powder at a calculated dosage of 50 mgm. dieldrin per square foot (chemical estimations yielded the very low average figure of 7·2 mgm. of dieldrin per square foot, but this was entirely incompatible with the calculated dosage). Results showed this insecticide to be the most efficient of those tested. For three months after treatment, mortalities among female *A. gambiae* and *A. funestus* were 100 per cent, and in the following six months they remained greater than 80 per cent. For the greater part of this period the majority of the mosquitoes collected were found dead inside the hut.

Little difference in the effects of the insecticides on *A. gambiae* and *A. funestus* females was observed. Against *Culex fatigans* all the DDT preparations gave very low kills (10–30 per cent), the BHC ones high initial kills (85 per cent in the first month, 7–30 per cent in months two to six) and dieldrin high, long-lasting kills (between 60 and 95 per cent for seven months after treatment).

In the later series of observations, *A. gambiae* and *A. funestus* females, caught from untreated houses in the area, were suspended in cages inside the huts without actual contact with the treated surfaces. After varying lengths of time the cages were removed and the mortalities among the mosquitoes determined 24 hr. later. The BHC preparations (P.520 and the oil-bound suspension) produced high kills among mosquitoes suspended for two to twelve hours for three months after treatment, especially among those nearest the treated surface. In two huts treated with DDT (the two Murphy formulations) the kills varied considerably but were generally low, even when the mosquitoes were left overnight (12 hr.). On the other hand, dieldrin produced very high kills among these suspended mosquitoes throughout the nine months observations.

DDT and dieldrin are both relatively non-volatile insecticides, and these kills among mosquitoes suspended without actual contact are probably due to the presence of airborne particles of the insecticides in the huts. If these particles occurred in similar numbers in both the huts treated with DDT and those treated with dieldrin, higher kills would be expected in those treated with dieldrin because of the greater toxicity of this insecticide.

Kills in the huts treated with BHC, where the insecticide is a volatile one, are probably due to a combination of fumigant and particulate effects.

In conjunction with these hut experiments, observations were also made on the resting times of individual mosquitoes on cardboard surfaces treated with the various insecticides. With all three insecticides, *A. gambiae* and *A. funestus* females were irritated by contact and after varying periods left the treated surface and flew towards light. These irritated mosquitoes were then caught and kept for 24 hr. and the mortality among them recorded. It was clearly demonstrated that a high proportion of these specimens were irritated and left a surface treated with DDT before they acquired a lethal dose of the insecticide. The longest contacts and the highest kills occurred with dieldrin, and slightly lower figures were recorded for BHC. With the mixture of BHC and DDT, a short contact occurred as with DDT alone, but a higher mortality was produced than with DDT alone. Table 2 summarizes the results obtained with surfaces treated with various formulations of the three insecticides in varying dosages up to two weeks after treatments.

TABLE 2

Insecticide	Total mosquitoes tested	Average contact time (min.)	Percentage mortality after 24 hr.
		A. gambiae	
BHC	51	22	75
DDT	71	8	82
BHC and DDT	7	8	57
Dieldrin	30	28	97
		A. funestus	
BHC	61	27	82
DDT	87	10	51
BHC and DDT	6	7	67
Dieldrin	17	36	94

A detailed account of these experiments, which were carried out on behalf of the Colonial Insecticides Committee, Colonial Office, London, is to be published shortly. [April 23.

'DOUBLE FRONTING' IN PAPER CHROMATOGRAPHY OF PROTEINS

By HANS G. BOMAN

Institute of Biochemistry, Uppsala, Sweden

DURING the first half of the present year, several authors have reported separations of proteins and enzymes by paper chromatography[1]. However, no investigations concerning the mechanism of this chromatographic process have as yet been published.

In this communication a few simple experiments are described which seem to indicate that there is a sort of 'double fronting' which appears to be the result of a displacing effect, and which has a great influence on the movement of the protein. Recently, E. Lester Smith[2] and also T. C. J. Ovenston[3] pointed out the possibilities of getting double zoning in partition chromatography. In spite of the analogy, it seems difficult to judge at present if the mechanisms in the two cases are similar.

The experimental procedure has been as follows. On a paper strip 12 cm. × 20 cm. (Whatman 54), six spots of commercial human serum albumin are placed on a line drawn obliquely across the paper (see Figs. 1–3). The chromatogram is then developed (temp. + 4° C.) with a mixture of 30 per cent ethanol and 70 per cent phosphate buffer ($\mu = 0 \cdot 10$), pH 7·7, and after the run the protein spots are made visible by staining with bromphenol blue[4]. Instead of falling on an oblique line as at the start, all the spots appear at the same distance from the front of the developing liquid (Fig. 1*b*). If the run is stopped at an earlier stage, the appearance of the chromatogram is somewhat different (Fig. 1*a*).

It is, however, also possible to apply the serum albumin behind the solvent front in the following way. The paper (without protein) is developed until

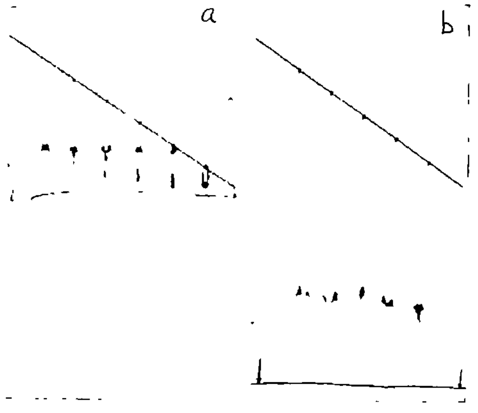

Fig. 1. Serum albumin placed on an oblique starting line and developed with ethanol and buffer (30 : 70)

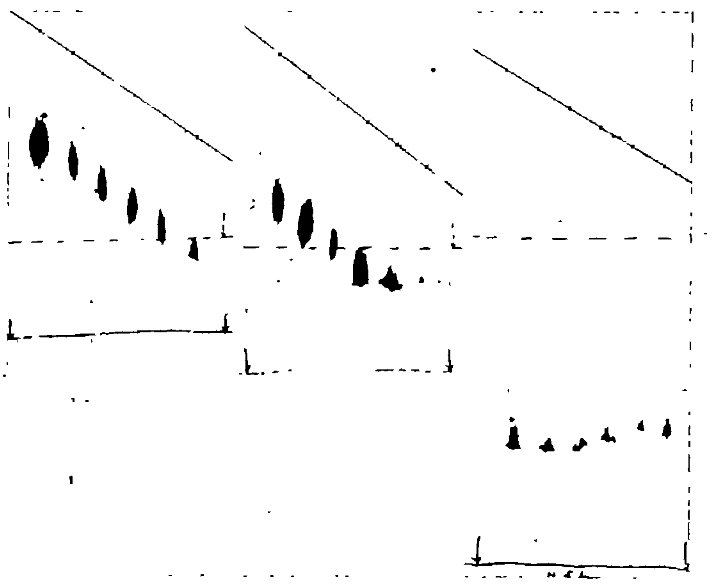

Fig. 2. Chromatograms with the albumin applied behind the solvent front

the solvent front has passed about 4 cm. beyond the last mark on the oblique starting line (that is, reached the dotted line in Fig. 2). The paper is then quickly taken out and serum albumin is applied to the starting marks by means of a capillary pipette. Development is then continued. Fig. 2 shows three such experiments which have been stopped at different times.

Two things may be specially noted. First, in the early stage of the process the spots occur obliquely, as is to be expected in ordinary chromatography, and have the usual oval shape. This gradually changes as if the spots were taken up by 'an invisible front' behind, but parallel to, the front of the developer. At the same time as the spots reach this 'front', they change to a more compressed shape. Secondly, all the oval spots are moving faster (R_F 1·2) than the front of the developing liquid, which means that part of the developer is adsorbed by the paper. This is in agreement with the results of Kowkabany and Cassidy[5].

Further, if, before the run, the paper is exposed to the atmosphere in the chromatographic vessel for at least eight hours, the adsorption of the albumin is decreased to such an extent that it follows the front of the developing liquid. In this way it is also possible for the albumin to pass the 'invisible front'. The rate of travel of this second front seems fairly constant; the R_F value as measured from the end of the paper is about 0·8.

These experiments can be explained as follows. Fig. 1*a* shows that at first the albumin travels closely behind the front, but that it is partly adsorbed on the paper. After a time, all the albumin has been adsorbed and the appearance of the chromatogram should be a series of narrow fingers of the same length (compare Fig. 3*a*). When, however, the developer travels through the paper, it causes some changes in it, possibly in the charge, which almost completely prevent serum albumin from being adsorbed behind this 'displacing front'. Thus the spots are taken up one by one by this front during the run. The shape of the spots also depends on the fact that the albumin is adsorbed before, but not after, this front. According to this view, the same changes in the paper should take place when it is exposed to the vapour.

In an early stage, when only some of the protein has been adsorbed and the 'displacing front' has passed the starting point, it is possible to get two spots (see Fig. 3*d*). In this way one can consequently split a homogeneous substance into two components—an artefact that may be of some interest.

As both serum albumin and the paper at *p*H 7·7 are negatively charged, *p*H changes towards the isoelectric point would be expected to cause increasing adsorption. Fig. 3 shows four chromatograms developed with the same concentration of ethanol (30 per cent) but with different phosphate buffers (μ = 0·10) : (*a*) *p*H 5·2, (*b*) 6·0, (*c*) 6·9 and (*d*) 7·7. It is easy to follow the decreasing effect of the 'displacing front' the more strongly the albumin is adsorbed.

Preliminary experiments have given the same result for another paper (Whatman 1) and for phycoerythrin using acetone buffer as the developing agent.

The phenomena described here indicate that great care must be exercised in the interpretation of the results obtained by filter-paper chromatography of proteins.

I wish to express my thanks to Prof. A. Tiselius for his interest and advice. [June 20.

Relativistic Theory of a Rigid Body

GARDNER[1] has recently given a new relativistic theory of a rigid body, and Synge[2] has applied this theory to the earth considered as a rigid body in rotation. He predicts, on the basis of the Gardner theory, that the fringes in a Michelson interferometer with one arm inclined at 45° to the horizontal should shift on rotating the interferometer about a vertical axis—provided that the interferometer is rigidly attached to the earth. The fringe shift predicted is $\left(\frac{E}{c}\frac{D}{\lambda}\right)\sin\theta$, where E is the velocity of earth's rotation, D is the length of the arm of the interferometer and θ is the angle between the projection of the direction of the inclined arm on a horizontal plane and a line pointing north[3].

We have made the following experiment to look for the predicted shift. A Michelson interferometer (made by Messrs. Hilger–Watts) was modified: (*a*) by mounting it on a suitable stand so that the arm along which the light enters is horizontal and the other arm is tilted so that the observer looks downwards along a line at 45° to the horizontal; (*b*) by clamping the movable carriage to the bed of the interferometer to give an arm of fixed length (approximately 12 cm.); (*c*) by extending the other arm to about the same length. The apparatus was clamped to the table of a large drilling machine. This table could be unclamped for rotation or clamped to the base of the drilling machine. The floor was of bituminous material, into which the feet of the machine were embedded. Underneath this was a concrete raft resting on earth.

The 5461-A. line of mercury obtained from a low-pressure source mounted on the drilling table was used. The instrument was adjusted to give about three straight-line fringes in the field of view. They could be regarded as localized on the mirror opposite the observer, who looked in through a pinhole. A line drawn in the silvering of the mirror was used as a reference mark.

The interferometer was arranged so that the observer looked along a line pointing westwards (and downwards). The position of the fringes was observed (1) with the table clamped and (2) with it unclamped. The table was then slowly rotated by hand, the observer viewing the fringes during rotation. When the table had been rotated through 90° so that the observer looked in a northerly direction, the rotation was stopped and the position of the fringes noted with the table clamped and with it unclamped. The table was then rotated through a further 90°, and the position of the fringes was again observed with the table clamped and with it unclamped.

The following results were obtained: (1) no significant change in the position of the fringes was obtained on clamping or unclamping the table, (2) during rotation the fringes vibrated with an amplitude of about 0·1 fringe, but on stopping the rotation they came to rest in the original position. In the best tests, a shift of 0·05 fringe should have been observable and no shift was observed. The shift calculated from the above formula is 0·42 fringe, and since 0·1 fringe could easily have been detected we conclude that the predicted shift does not take place.

We wish to thank Prof. J. L. Synge for a private communication in which he discussed the conditions to be fulfilled in testing the theory.

Permafrost Drilling and Soil-Temperature Measurements at Resolute, Cornwallis Island, Canada

IN August 1948, a drilling programme was carried out at Resolute, N.W.T., Canada, lat. 74° 41′ N., long. 94° 54′ W., to locate a suitable site for a future seismological station. When this had been completed, a series of shallow holes was drilled about 100 ft. north of the weather station operations building, and ceramic resistance thermometers were inserted at depths of 8, 18, 39 and 60 in.

In 1950 it was decided to extend the scope of this investigation and attempt to obtain information from much greater depths in the permanently frozen ground. A maximum depth of 1,000 ft. was set as the objective. This project was made possible by the joint efforts of the Meteorological Division of the Canadian Department of Transport, the United States Weather Bureau, and the Dominion Observatory of Ottawa, Canada.

To begin each hole, a 2½-in. pipe was driven to bedrock with a 350-lb. hammer. It was found in each case that the overburden was approximately 6 ft. thick and consisted of frozen gravel. The bedrock was limestone with occasional faults and cracks. The drill hole had a diameter of 1½ in. and recovered core with diameter 15/16 of an inch.

Holes were drilled to depths of 6, 11, 23, 30, 50 and 103 ft. and cables with temperature elements were inserted in each. All the core was recovered from the 103-ft. hole. The most serious problem encountered was the maintenance of an adequate circulation of hot water in the drill hole to prevent frost formation.

An improved hot-water boiler and pumping equipment were provided in 1951 and a further attempt was made to drill to a depth of 1,000 ft. Water for the drilling was obtained by pumping it directly from a lake 1,500 ft. distant, and drilling operations were carried on around the clock. As the drilling proceeded to greater depths, the circulating water had to be heated to a correspondingly higher temperature. The valves and plungers of the pump did not stand up too well under the increased heat and pressure, and breakdowns occurred frequently.

Out of a total of seven holes which were drilled during the period from the first week of July until August 20, five holes were lost. Three were lost due to cave-in, another owing to breakdown of the pumping equipment, and the fifth when mud formed at the bottom of the hole and the line pressure was insufficient to wash the mud to the surface.

The remaining two holes were drilled to depths of 307 ft. and 453 ft. respectively. Thermistor elements were lowered into each of these and regular temperature readings are being taken. The 453-ft. hole was completed in four days. A greater depth could have been reached; but so much drilling equipment had been lost in the other holes that no drill rods were available to progress farther. A continuation of the permafrost drilling programme is being carried out during the present summer, when it is hoped that the objective of 1,000 ft. will be reached.

The average conductivity of the bedrock as determined from the core samples by Prof. A. D. Misener, of the University of Western Ontario, London, Ontario, is :

$$K = 0\cdot0066 \text{ c.g.s. units at } 31\cdot2^\circ \text{ C.}$$

A thorough analysis has not been made as yet of the soil temperature observations from Resolute. Nevertheless, a number of interesting features has been noted.

(1) The temperatures at the 8-in. level show short-period fluctuations which reflect the fluctuations of the air temperature above the surface. However, these fluctuations from ambient air temperatures are rapidly damped out with increasing depth and are practically negligible at the 60-in. level.

(2) There is a marked lag in seasonal temperature changes with depth. For example, the temperatures at the 8-in. and 18-in. levels reach a maximum about the second week in August, whereas the temperature at the 60-in. level continues to rise until mid-September. The temperatures from the surface to the 60-in. level fall at varying rates after mid-September, so that by the last week in September there is a reversal in sign of the temperature gradient.

(3) The temperatures in the layers near the surface begin to rise in early March, and about May 1 there is again a reversal in sign of the temperature gradient from the surface to the 60-in. level.

(4) From about August 25 to September 15, the temperatures within 18 in. of the surface remain near the freezing point, indicating that the complete freezing of the water in the active layer takes about three weeks.

(5) The temperatures at the 98-ft., 300-ft. and 450-ft. levels remain practically constant with the following values: 98 ft., $-13\cdot50^\circ$ C.; 300 ft., $-11\cdot59^\circ$ C.; 450 ft., $-9\cdot54^\circ$ C.

(6) The layer from 50 ft. to 98 ft. is nearly isothermal.

(7) Seasonal temperature changes are perceptible to near the 50-ft. level; but the lag at this level amounts to about six months.

Reaction between Diethyl Peroxide and Nitric Oxide

In the hope of trapping the radicals probably produced during the photolysis of diethyl peroxide, the vapour of the latter was mixed with a several-fold excess of nitric oxide in a 3-litre 'Pyrex' bulb. The mixture was then passed through a water-cooled helical silica tube surrounding a mercury arc into a trap immersed in 'Drikold'. Suspiciously large amounts of ethyl nitrite were found in the trap, and even larger quantities were collected in a blank run without the arc. After the mixture had been stored in the dark for twenty-four hours, spectrophotometric examination showed that a major portion of the peroxide had been converted into nitrite.

The inhibition by nitric oxide of the thermal decomposition of diethyl peroxide[1] is clearly no evidence for a free radical mechanism.

Inhibition of the Thermal Decomposition of Diethyl Peroxide

The mechanism of the thermolysis of diethyl peroxide is uncertain. Harris and Egerton believed the reaction to be a straightforward, unimolecular decomposition, although they observed short induction periods with some samples and generally much longer ones in the presence of nitric oxide[1]. The products suggest the occurrence of reactions involving free radicals, and in the opinion of Neumann[2] the decomposition is a chain reaction. It is, however, difficult to reconcile a significant participation of free radicals in the decomposition with the first-order kinetics and the low activation energy (c. 31 k.cal.); compared with accepted dissociation energies of O—O bonds (HO—OH, 54 k.cal.[3], *t*.BuO—O*t*.Bu, 39 k.cal.[4]).

A re-examination of the reaction in a spherical 2-litre 'Pyrex' vessel using peroxide pressures of a few millimetres of mercury has, in the main, confirmed the results obtained by Harris and Egerton. Our velocity constants, derived from initial rates, were however about 25 per cent greater than those of Harris and Egerton, and the activation energy, a little smaller. An appreciable reaction of zero order appeared to be superimposed on the first-order reaction at temperatures below 160° C. During the course of individual reactions, the first-order law was not well obeyed by the pressure change, and the energy of activation derived from the 'half lives' of the pressure change were considerably less than that obtained from the initial rates, and was, indeed, close to the value of about 22 k.cal. obtained by Russian authors[2].

When hydrogen iodide was added to the peroxide vapour at c. 140° C., the rate of change of pressure was reduced and iodine was formed. Excess hydrogen iodide reduced the rate to zero. Addition of iodine also inhibited the pressure change, although not completely, a limit of about 40 per cent of the uninhibited rate being attained with excess iodine.

In view of the reaction observed with nitric oxide[5], caution is required in the interpretation of these observations, which are being extended.

A New Method of Melting Ferromagnetic Semiconductors. $BaFe_{18}O_{27}$, a New Kind of Ferromagnetic Crystal with High Crystal Anisotropy

In recent years, ferromagnetic oxides have become of great interest for electrotechnical applications[1,2]. They are used in the form of polycrystalline sintered materials. In order to get a better insight into the properties of the material itself, without the additional influence of air pores, we started to prepare these oxides from the melt. Moreover, we hoped to grow from these melts single crystals large enough for magnetic measurements.

Smiltens *et al.*[3] melted magnetite, Fe_3O_4, in an electric furnace at about 1,600° C. By moving the platinum crucible through a temperature gradient, large single crystals were obtained. Galt *et al.*[4,5] grew small single crystals of nickel ferrite and manganese zinc ferrite from a borax melt.

We have applied the high-frequency melting technique common in research on metals. Special problems arise in using this high-frequency technique when dealing with oxides, which are mostly semiconductors with a high resistivity at room temperature. All ferromagnetic materials investigated were composed of several oxides, one of which was always iron oxide. As magnetite is an iron oxide with a relatively low resistivity ($\rho = 0{\cdot}01$ ohm cm. at room temperature[6]) it has been used as a starting material for the melts, instead of α-Fe_2O_3.

In order to prevent oxidation of the material and the resultant loss of conductivity during heating, the melting process is carried out in a nitrogen atmosphere containing less than 10^{-4} parts of oxygen. Sintered magnetite disks are placed in a quantity of a metal oxide powder such that the desired ratio of the metal ions in the final product is obtained. When the contents of the crucible have completely melted in the nitrogen atmosphere, this atmosphere is gradually changed to the equilibrium oxygen atmosphere of the ferromagnetic oxide at its melting point. The conductivity of the ferromagnetic oxides in the neighbourhood of this temperature is sufficiently high to make the high-frequency induction currents keep these oxides in the molten state. An advantage of this method of melting is the possibility of inserting the high-frequency coil in a high-pressure apparatus, so that when the contents of the crucible have melted in a reducing atmosphere, the nitrogen can be replaced by oxygen at a pressure much higher than atmospheric. Another advantage is that it is not the crucible itself that is directly heated, but its contents; thus the crucible has a slightly lower temperature than is the case when using the electric furnace technique, and thus contamination of the melt by the crucible material will be slower. Several kinds of crucibles have been used, the best results being obtained with one of alumina preheated to a temperature slightly below its melting point. The top of the melt was kept at the same or even at a higher temperature than the bottom by putting a disk of rhodium or iridium metal as a lid upon the crucible. In the high-frequency field, this metallic disk attains a higher temperature than that of the contents of the crucible, thus causing additional heating of the surface.

Disk-shaped surface crystals grow when the melting process described above is followed by a reduction of the high-frequency current and consequent slow cooling below the temperature at which the contents solidify. The accompanying illustration is a photograph of the surface of the contents of the crucible, showing several crystals of manganese ferrite (diameter of the crucible 32 mm.). One of these materials has a [100] plane parallel to the surface, while all other planes shown are [111] planes.

Surface of the contents of a crucible showing several disk-shaped single crystals of manganese ferrite (crucible diameter, 32 mm.)

Magnetite crystals containing less than 2 per cent ferrous ions in excess are obtained from the melt if the melting process is carried out in an atmosphere having less than about 10^{-4} atm. oxygen pressure. In order to prevent oxidation during cooling, the melt is rapidly cooled (within 10 min.) from just below the melting point (1,600° C.) to about 1,000° C., after which it is cooled to room temperature in about five hours. The equilibrium oxygen pressure at the melting point appeared to differ greatly from that given by Darken and Gurry[7] (about 0·06 atm. oxygen), but is in good agreement with the figure given by Smiltens[3]. The equilibrium atmosphere of manganese ferrite at its melting point (1,600° C.) appeared to be about 1 atm. of oxygen (crystals containing 0·17 per cent ferrous ions by weight were obtained), which was also found recently by Gurry and Darken[8].

Another interesting ferromagnetic material is $BaFe_{12}O_{19}$, which has a hexagonal structure[2] and shows a very high magnetic crystal anisotropy. Experiments on the melting of magnetite with different amounts of barium carbonate gave three kinds of hexagonal phases with different *c*-axes, respectively 23·2, 32·8 and 28 A. Mostly these phases formed thin alternating layers of parallel-oriented crystals, and a single type of crystal could not be separated. Braun (see ref. 2) found that the first kind has the magnetoplumbite structure already described by Adelskold[9]. From a melt of 12 gm. Fe_3O_4 and 1·8 gm. $BaCO_3$ in oxygen, a single crystal with a *c*-axis of 32·8 A. was separated. The dimensions of this crystal were 4 × 5 × 0·3 mm. An account of the X-ray examination of this crystal is given by Braun[10]. This crystal proved to have the composition $BaFe_{18}O_{27}$ and a structure resembling that of $BaFe_{12}O_{19}$. It has the hexagonal axis perpendicular to the surface of the disk, and in a homogeneous magnetic field this *c*-axis becomes oriented parallel to the lines of force, which suggests a very strong crystal anisotropy. Results of magnetic measurements are given elsewhere[2].

I wish to thank Dr. J. J. Went for his interest and advice during the experiments.

Crystal Structure of BaFe$_{18}$O$_{27}$

IN the course of an investigation[1] into the properties of substances with magnetoplumbite structure[2], Wijn[3] of these laboratories tried to prepare single crystals of BaO.6Fe$_2$O$_3$. Mixtures of barium oxide and magnetite (Fe$_3$O$_4$) were melted and slowly cooled. In one of these melts a single crystal of about 4 × 5 × 0·3 mm.^{3} developed.

The results of the X-ray investigation of this crystal are shown below. The notation used is that of the "International Tables for the Determination of Crystal Structures" (1935).

Composition, BaFe$_{18}$O$_{27}$
$a = 5{\cdot}88$ A. $c = 32{\cdot}84$ A.

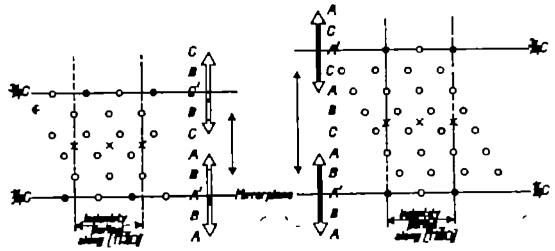
2 Ba	on	2(*b*)		
2 Fe	,,	2(*d*)		
4 Fe	,,	4(*f*)	$z = 75°$	
4 Fe	,,	4(*e*)	$z = 20°$	
4 Fe	,,	4(*f*)	$z = \overline{26{\cdot}8}°$	
4 Fe	,,	4(*f*)	$z = 33{\cdot}5°$	
6 Fe	,,	6(*g*)		
12 Fe	,,	12(*k*)	$z \sim \overline{54}°$	$x \sim 60°$

Space group $C6/mmc$
2 formula units per cell

6 O	in	6(*h*)		$x \sim 180°$
12 O	,,	12(*k*)	$z = 64{\cdot}5°$	$x \sim 60°$
4 O	,,	4(*f*)	$z = \overline{64{\cdot}5}°$	
12 O	,,	12(*k*)	$z = 40°$	$x \sim 180°$
4 O	,,	4(*e*)	$z = \overline{40}°$	
12 O	,,	12(*h*)	$z = \overline{13}°$	$x \sim 60°$
4 O	,,	4(*f*)	$z = 13°$	

The magnetoplumbite structure can be described as consisting of spinel-like blocks, with the thickness of four oxygen layers, linked together by layers in which one oxygen has been replaced by barium. The linking layer is hexagonally packed with respect to its neighbouring layers. Moreover, it contains an iron atom surrounded by five oxygen atoms in a trigonal dipyramid.

The new structure described here is built along the same lines. The spinel block has not four but six oxygen layers, the Ba/Fe ratio now being 1/18.



BaFe$_{12}$O$_{19}$ — Two formula units per cell

BaFe$_{18}$O$_{27}$(16Fe^{3+},2Fe^{2+}) — Two formula units per cell

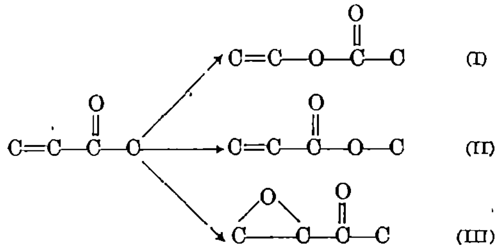
Peroxidation of Unsaturated Ketones

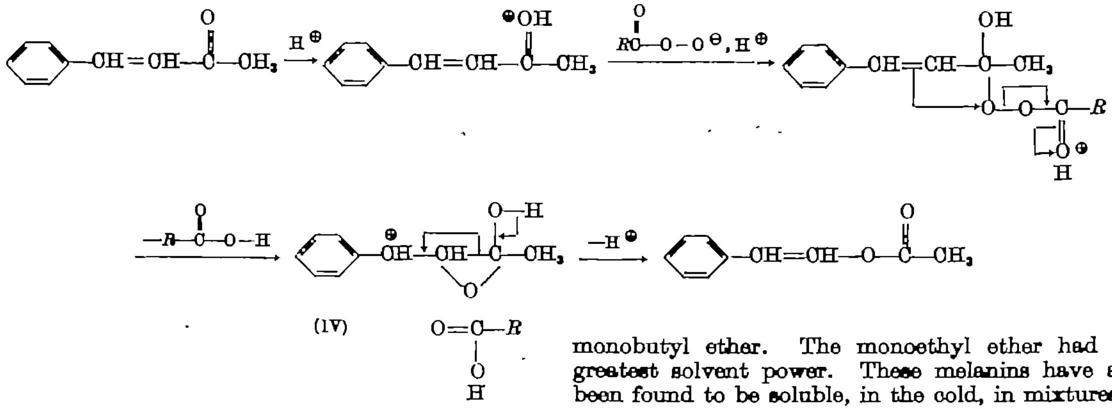
Two recent reviews of peroxidation of organic compounds[1,2] cite the fact that α,β-unsaturated ketones are oxidized by peracids to enol esters. *A priori*, however, one might expect one or more of three possible products and their hydrolysates.



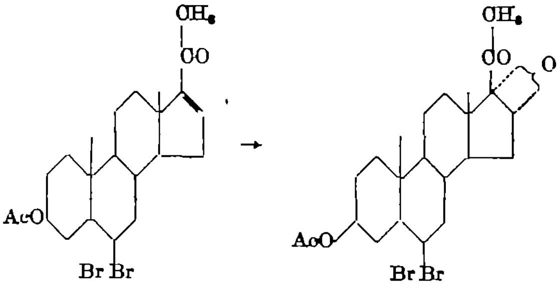
Thus, I and II would result from an attack of peracid at the carbonyl carbon followed by rearrangement according to the mechanism proposed by Criegee[3], Friess[4], and Doering[5], while III would be the consequence of an attack at the β-carbon of the conjugated system.

With the exception of a few peroxidation reactions in the terpene field, only three main examples[6–8] of this process appear in the literature, and in all three cases the starting compounds possess a phenyl group in the β-position. On applying the accepted mechanism[3–5] to this system (for example, benzalacetone), it becomes apparent that the transition state involves a mesomeric benzyl carbonium ion (IV) if the electron-rich carbon–carbon double bond is permitted to participate in breaking the peroxide linkage. Since (IV) constitutes a low-energy state, it would be expected that the above transition requires less activation energy than either the migration of the methyl group (to yield II) or an original attack of the peracid molecule on the β-carbon (to yield III). Thus, it might be predicted that any α,β-unsaturated carbonyl system containing a substituent in the β-position, which has the power of stabilizing a carbonium ion there, would yield an enol ester or lactone on peracid oxidation. Furthermore, systems not having this property might be expected to yield the same, and/or α,β-unsaturated esters or lactones and/or α,β-epoxy-ketones.

Julian's perbenzoic acid oxidation[9] of 5,6-dibromo-16-pregnen-3β-ol-20-one acetate (V) to the 16,17-oxido compound (VI) lends some credence to the above argument. Likewise, preliminary experi-



ments of an extensive research of the peracid oxidation of unsaturated ketones in these laboratories have yielded similar results; for example, an α-phenyl-α,β-unsaturated ketone reacted with peracetic acid giving a mixture consisting mainly of compounds II and III. It is hoped to report on the outcome of these investigations in due course.



(V) (VI)

Solubility of Melanins

IN further attempts to find a solvent for melanin which would be of use in histological work, the following substances have been found to dissolve, in the cold, the pigments extracted from the ink sac of *Sepia officinalis* and melanoma tissue, and those prepared from adrenaline and 3,4-dihydroxyphenylalanine (dopa): ethylene glycol monomethyl ether, ethylene glycol monoethyl ether, and ethylene glycol monobutyl ether. The monoethyl ether had the greatest solvent power. These melanins have also been found to be soluble, in the cold, in mixtures of ethyl lactate and benzyl alcohol, the best proportions being 6 of the former to 4 of the latter (by volume). In all these solvents the solubilities of sepia, melanoma and adrenaline melanins were, so far as could be determined from what must be regarded as impure specimens, of the same order, but the melanin from 3,4-dihydroxyphenylalanine was much less soluble than the others. However, these solvents failed to dissolve the melanin in sections of melanoma tissue, even with the aid of heat. The method used for extracting the sepia and melanoma melanins was: (1) solution in 10 per cent aqueous sodium hydroxide, (2) filtration and precipitation of the melanin by dilute hydrochloric acid, (3) removal of extraneous fatty substances by extraction with ethyl alcohol, chloroform and benzene, (4) repetition of (1) and (2). This extraction procedure was also applied to melanins from 3,4-dihydroxyphenylalanine and adrenaline, but in spite of this uniformity of treatment the former product was still the least soluble of the four types of pigment.

Millott and Jacobson[1] have recently directed attention to the variations in the solubility of melanin as described by different workers in this field. In the case of sepia and melanoma melanins, as compared with that from 3,4-dihydroxyphenylalanine, these differences in solubility may well be due to combination of the pigment with other intracellular substances, probably proteins. (Preliminary experiments have suggested that sepia melanin has a molecule approximately twice the size of that from 3,4-dihydroxyphenylalanine[2].) This does not explain the difference in solubility between 3,4-dihydroxyphenylalanine and adrenaline melanins; but this may be due to the persistence of the methyl group, attached to the indole nitrogen, in the adrenaline product[3].

Two conclusions appeared to be justified: (1) removal of melanin from the ink sac of *Sepia officinalis* and melanoma tissue by the method described above altered its chemical composition; and (2) these melanins, after taking into consideration this effect of extraction, are not identical with that derived from 3,4-dihydroxyphenylalanine.

The work has been carried out with the aid of a grant from the Government Grant Committee of the Royal Society.

Action of X-Rays on Aqueous Solutions of Perchloric Acid

IN the study of the radiation chemistry of metal ions in solution, it may seem desirable to use perchloric acid solutions because it is generally assumed that perchlorate ions show relatively little tendency to complex formation.

However, as was found recently[1], perchlorate in aqueous solutions is decomposed by the action of X-rays into chlorate and oxygen. Fig. 1 shows that the amount of chlorate formed in the irradiation of aqueous solutions of perchloric acid by X-rays (200 kV.) is directly proportional to the concentration of the perchloric acid. While the addition of ceric salts to the solution does not influence the formation of chlorate (see Fig. 1), if ferrous salts are present in the solution, chloride is formed in an amount which is equivalent to the chlorate formed in the absence of ferrous salt, under otherwise similar conditions.

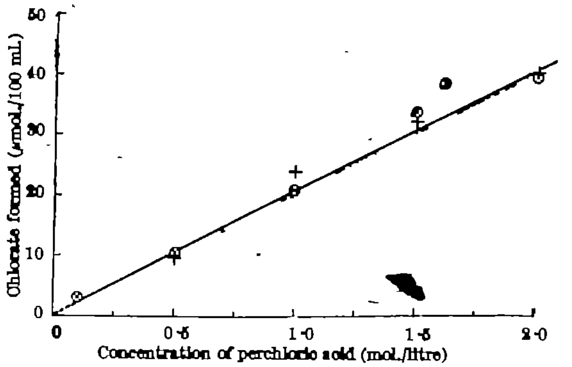

Fig. 1. Dependence of the formation of chlorate on the concentration of perchloric acid. Irradiation with X-rays (200 kV.) at constant dose of 2×10^5 e.u., in the presence of air. (1 e.u. ≡ 93 ergs/ml.) ○, aqueous perchloric acid, +, aqueous perchloric acid in the presence of ceric perchlorate ($3{\cdot}17 \times 10^{-4}$ *M*)

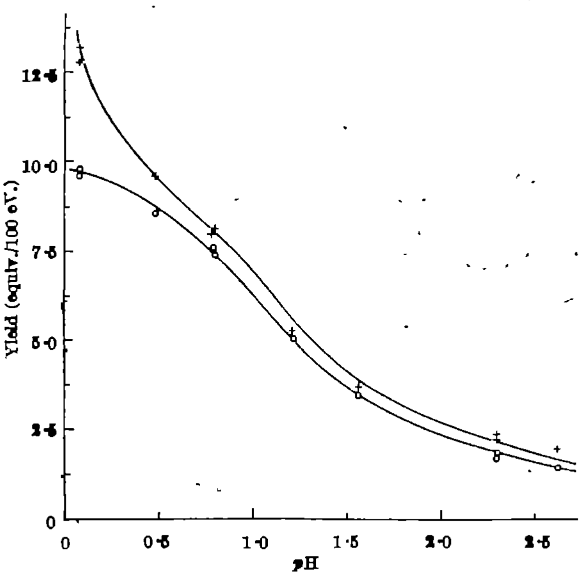

Fig. 2. Dependence of the yield of ferric salt (+) and of hydrogen (○) formed in the irradiation of ferrous perchlorate (0·01 *M*) in evacuated solutions at different concentrations of perchloric acid (as indicated by the *p*H). X-rays (200 kV.); constant dose of about $8{\cdot}70 \times 10^5$ e.u.

Fig. 2 shows some of the results obtained in the system ferrous perchlorate – perchloric acid. In this case, particularly at the higher perchloric acid concentrations, the results do not show the normal features of the radiation chemistry of the ferrous–ferric system[1]. Whereas in the irradiation of ferrous sulphate in sulphuric acid solutions, *in vacuo*, the amount of hydrogen gas formed is equivalent to the amount of ferric salt produced[1], this is no longer true in perchloric acid solutions where, under similar conditions, less than the equivalent amount of hydrogen is produced.

The general conclusions which can be drawn from these results are again in agreement with the assumption that the energy absorbed by the water leads to the net decomposition: $H_2O \xrightarrow{\sim\sim} H + OH$, resulting in the formation of hydrogen atoms and hydroxyl radicals[2], which, however, under the conditions in question, seem to be unable to react with the perchlorate.

As pointed out above, the amount of chlorate formed is directly proportional to the concentration of the perchlorate. This would be in agreement with the assumption that its formation is due to a 'direct' effect, that is, to the radiation energy which is absorbed by the perchlorate itself. It is conceivable that this mechanism involves the formation of an unstable intermediate leading to the formation of chlorate (which is not influenced by ceric salts) and which in the presence of ferrous salts is further reduced to chloride.

A full account will be published elsewhere.

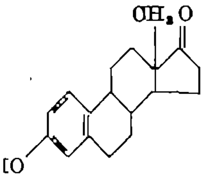
A New Route to Œstrone

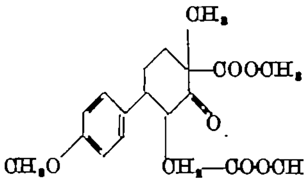
IN a recent paper, Johnson and Christiansen[1] have reported a new total synthesis of œstrone (I) from the keto-diester (II).

For a number of years we have been engaged in the study of the Friedel–Craft reaction with the view of preparing compounds of type II. We have already reported[2] the synthesis of 4-methyl-4-carbethoxy-(*p*-methoxyphenyl)-cyclohexan-3-one (IV) by Friedel–Craft condensation between anisole and 4-methyl-4-carbethoxycyclohexene-3-one (III). In the present communication, the study of the condensation of methyl 4-methyl-4-carbomethoxycyclohexene-3-one-2-acetate (V, $\lambda_{max.}$ 235 mμ, log ε 3·8) with anisole is reported. The reaction was carried out in the cold with a solution of (V) in anisole in a slow stream of dry hydrogen chloride and in the presence of anhydrous aluminium chloride. The condensation product, obtained as a glass, was hydrolysed and decarboxylated in 80 per cent yield to give a mixture of two isomers of 4-methyl-(*p*-methoxyphenyl)-cyclohexan-3-one-2-acetic acid (VI, *A* and *B*, melting points 208° and 135°) in the ratio 1 : 7, respectively. The isomer *B* was also obtained by Johnson and Christiansen by the hydrolysis of their keto-diester II (private communication). A direct comparison of the mixed melting point of our isomer *B*, melting point 135° with an authentic specimen, kindly supplied by Dr. W. S. Johnson, showed no depression. The recent successful conversion of (II) to œstrone (I) makes further work in this line unnecessary.

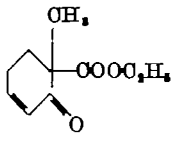
The unsaturated keto-ester (V) was prepared by the following method. Methyl hexane-1,2,6-tri-



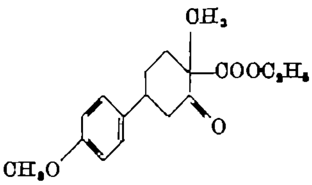
(I)



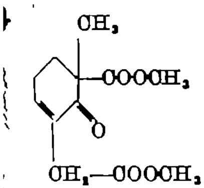
(II)



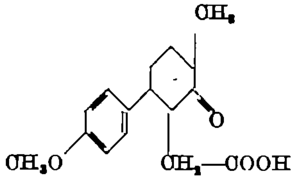
(III)



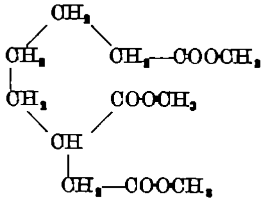
(IV)



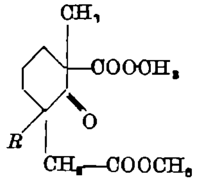
(V)



(VIA, m.p. 208°
VIB, m.p. 185°)



(VII)



carboxylate (VII), prepared from ethyl 2-carbethoxycyclohexanone-2-acetate[3], was cyclized in benzene solution with sodium dust in an atmosphere of nitrogen, and the resulting sodio derivative was directly treated with an excess of methyl iodide to furnish the methylated β-keto-ester (VIII, *R* = H; $n_{D}^{29°}$, 1·4649) in 88 per cent yield. This ester reacted smoothly with a molar quantity of bromine in carbon tetrachloride solution to give the solid bromo compound (VIII, *R* = Br; melting point 94–95°) in 80 per cent yield. The latter on dehydrobromination by treatment with dimethylaniline gave methyl 4-carbomethoxycyclohexene-3-one-2-acetate (V, $n_{D}^{29°}$, 1·5141) in 75 per cent yield.

In view of the good yield in each step of the above preparation, the present method for the preparation of the key intermediate II, in the synthesis of œstrone (I), appears to be an attractive one.

Our thanks are due to Dr. D. K. Banerjee, professor of organic chemistry, College of Engineering and Technology, Bengal, for his suggestions, and to Dr. William S. Johnson, of the University of Wisconsin, for supplying an authentic specimen of VI, *B*.

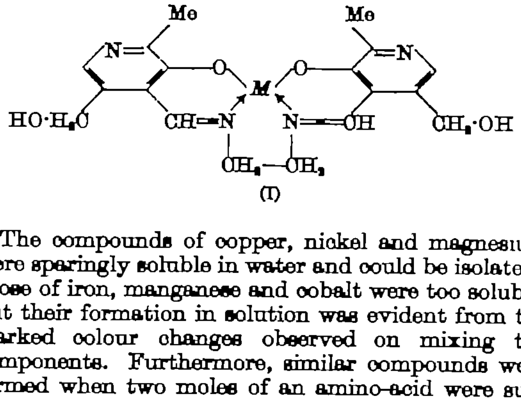
Pyridoxal Derivatives in Transamination

IN living systems a transfer of amino groups occurs between certain amino-acids and keto-acids. This important reversible process, known as 'transamination'[1], effects a link between carbohydrate and protein metabolism, and the responsible enzymes, the transaminases, are activated by pyridoxal[2] or pyridoxamine phosphates[3]. The proposed mechanisms of the reaction involve participation of a Schiff base between amino- and keto-acids[4] or between amino-acids and pyridoxal phosphate[5]. Prototropic rearrangement followed by hydrolysis gives, respectively, the keto- and amino-acids or the keto-acid and pyridoxamine phosphate, the latter then undergoing a reverse reaction with a different keto-acid. A reversible, non-enzymic reaction between pyridoxal and amino-acids to give pyridoxamine and keto-acids, discovered by Snell[6], was shown recently to be catalysed by trace metals (copper, iron, aluminium)[7]. Interest in this chemical process lies mainly in its possible connexion with the biological one; therefore an explanation of the part played by metals in such reactions is clearly desirable.

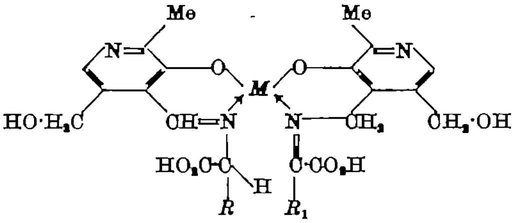
Pyridoxal is a typical phenolic aldehyde, resembling salicylaldehyde in many of its reactions. It has been found that this similarity can be extended to the formation of metallic complexes between pyridoxal, ethylenediamine and metal salts. These co-ordination compounds are analogous to those formed with salicylaldehyde[8] and have the probable structure (I).



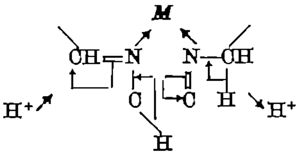
(I)

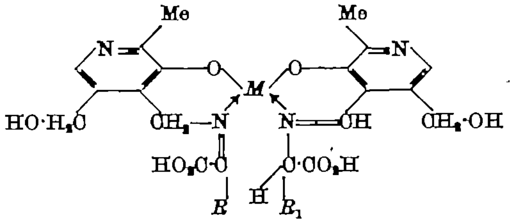
The compounds of copper, nickel and magnesium were sparingly soluble in water and could be isolated; those of iron, manganese and cobalt were too soluble, but their formation in solution was evident from the marked colour changes observed on mixing the components. Furthermore, similar compounds were formed when two moles of an amino-acid were substituted for the ethylenediamine. Pyridoxal formed green copper complexes with all the amino-acids examined (glycine, alanine, serine, lysine, *iso*leucine, valine, threonine, methionine). In most cases these were too soluble for isolation, but their formation was observed by the characteristic green solutions produced on mixing the components (in the absence of pyridoxal the typical deep-blue copper-amino-acid complexes were produced). The green colour persisted in acetic acid solution but was destroyed by mineral acids. The tyrosine compound was sufficiently insoluble for isolation (found C, 45·6; H, 5·0; N, 8·4; Cu, 14·5; $C_{34}H_{38}O_{10}N_4Cu_2 6H_2O$ requires C, 45·6; H, 4·9; N, 6·3; Cu, 14·3 per cent).

In view of the ready formation of such compounds, it is possible that, in a solution containing pyridoxal, pyridoxamine, an amino-acid and a keto-acid, mixed co-ordination compounds of the type (II) would be formed. The sharing of the lone electron pairs of the two nitrogen atoms with the metal would facilitate the release of protons from the α-position of the amino-acid residue, and from the methylene group adjacent to the aromatic ring in the pyridoxamine moiety. Electronic displacements might then occur as indicated, giving rise eventually to (III). Hydrolysis of (III) would complete the transamination. The process would be reversible and an equilibrium state attained.



(II)





(III)

In the non-enzymic reaction only two components, together with cations, were required; for example, pyridoxal and an amino-acid. However, the other components necessary for the formation of (II) could be formed to a small extent in the initial stages by spontaneous reaction.

The significance of these proposals in biological transamination is not yet clear. Cations are known to be essential for the proper functioning of many enzymes, but the transaminases have not yet been obtained sufficiently pure to ascertain their cation requirements. If a similar mechanism does operate, then it becomes possible to ascribe functions to most of the groups in the coenzymes. The aldehyde (or amino) and phenolic groups would be involved in the transamination proper, while the ring nitrogen and phosphate group (on the 5-hydroxymethyl) would participate in electrovalent linkage with a protein.

Thanks are due to Roche Products, Ltd., for a gift of pyridoxal.

Production of Antibiotic Substances by the Roots of a Grass (*Trachypogon plumosus* (H. B. K.) Nees) and of *Pentanisia variabilis* (E. Mey.) Harv. (Rubiaceæ)

DURING the course of a study of the rate of nitrification in soils taken from plant communities representing various stages of the secondary grassland succession on the Transvaal Highveld, it was found that soils taken from the *Trachypogon plumosus* grassland climax community showed a consistent lag in the production of nitrate.

The experimental methods were as follows. (1) Soils were moistened and incubated for several weeks; the flasks were weighed initially, and reweighed from time to time, the loss of weight being made up with distilled water. These soils were then analysed for nitrate-nitrogen and ammonium-nitrogen. (2) Soil columns were perfused with distilled water using the Lees and Quastel perfusion technique. The perfusate was analysed for nitrate-nitrogen and ammonium-nitrogen from time to time. (3) Whole plants with their surrounding soil cores were placed in large pots. The aerial parts were removed completely, leaving an undisturbed soil and root system in the pots. Rain-water that percolated down through the soil cores was collected and analysed for nitrate-nitrogen and ammonium-nitrogen. Botanical analyses were carried out on the soil surfaces of the pots from time to time as plant growth regenerated.

It was found that, in the pots containing the *Trachypogon plumosus* root and soil, (*a*) little or no nitrate was produced; (*b*) the regeneration of plant growth was practically negligible.

It was thought from these observations that the roots of *Trachypogon plumosus* were secreting antibiotic substances which were inhibiting the activity of nitrifying organisms, and also seemed to be inhibiting the germination of weed seeds, and the growth of weed seedlings.

Roots of *Trachypogon plumosus* were collected, washed free of all soil particles and an extract was made with distilled water. This extract was tested by the agar cup method on plates seeded with *Escherichia coli*, *Bacillus subtilis*, *Staphylococcus aureus* (Oxford strain) and *Streptococcus hæmolyticus* (Richard strain). Very clear, wide zones of inhibition were displayed on all plates. So far as we know, this is the first instance where grass roots have been shown to exhibit antibiotic properties.

The possibility of other plants in this community containing antibiotic substances arose, and several grasses and non-grasses were treated accordingly. Three other non-grass plants were found to show antibiotic activity. Two of them displayed only slight activity against *E. coli* and *B. subtilis*, but *Pentanisia variabilis* (Rubiaceæ) showed very marked activity against *E. coli* and *B. subtilis*, and slight activity against *Staphylococcus aureus* and *Streptococcus hæmolyticus*.

An antibiotic assay of most of the important plants growing in the *Trachypogon plumosus* grassland climax community is at present being carried out. Further work on the antibiotic principle of *Trachypogon plumosus* and its effects on nitrifying organisms and weed seeds is proceeding.

Microbiological Decomposition of Malto- and Lacto-bionate

Stodola and Lockwood[1], and Kluyver, De Ley and Rijven[2], demonstrated that several species of *Pseudomonas* are able to oxidize maltose and lactose to the corresponding malto- and lacto-bionic acid, by oxidation of the reducing group of the disaccharide, without breaking the oxygen bridge. Some strains of *Pseudomonas* consume the calcium salt of these acids slowly[2]. *Pseudomonas* is a common surface inhabitant of several natural waters, so it is likely that under these natural conditions these cells may convert maltose from polysaccharides (formation of lactose is improbable) into the corresponding acid. It seemed to be of interest to ascertain what kind of micro-organisms are endowed with the ability to consume maltobionate, with the view of getting an idea of the importance of this decomposition process in Nature. Lactobionate was included in view of a future study of the enzymatic mechanism of its breakdown.

Petri dishes, containing agar, with potassium, ammonium and magnesium sulphates, yeast extract, calcium carbonate and a calcium bionate, were inoculated with ditch- and river-water, stagnant water, soil, humus, dune-sand, etc., and incubated, usually at 25°–30° C., one set aerobically, another anaerobically. Growth in anaerobic conditions was scanty, and only a few colonies developed on bionates. On the other hand, there was a luxurious aerobic growth on bionates and a great variety of microflora developed. Of these, more than sixty strains have been isolated and investigated. These strains quickly consume malto- or lacto-bionate, or both, in a liquid culture medium when incubated for plentiful aeration in a shaking device in an incubator room at their optimal temperature. The consumption of bionates was determined by the titrimetric method of Kluyver, De Ley and Rijven[2]. The accompanying list indicates the bacteria found (nomenclature according to "Bergey", 6th edit. ; quantitative data will be published elsewhere) : *Escherichia freundii* or *intermedium* ; *Paracolobactrum aerogenoides* ; *Aerobacter aerogenes* ; *Aerobacter cloacae* ; *Serratia plymuthicum* ; *Alcaligenes faecalis* ; *Achromobacter* sp. ; *Flavobacterium* sp. ; *Corynebacterium simplex* and *helvolum* ; *Pseudomonas fluorescens* and sp. ; *Bacillus megatherium* and *circulans*. Several other bacteria, as yet unidentified, are able to consume malto- and/or lacto-bionate. Usually several different strains of the same micro-organism were isolated. *E. coli* strains are unable to consume maltobionate ; some decompose lactobionate slowly. Most of the above-mentioned strains decompose both bionates. Only maltobionate can be broken down under anaerobic conditions by some strains of *Aerobacter*. The following moulds decompose maltobionate : *Penicillium* sp. ; *Hormodendrum cladosporoides* ; *Aspergillus* sp. ; *Fusarium merismoides, avenaceum* and *oxysporum*. It is remarkable that no yeasts were detected.

Most of the bacteria grow well on the corresponding disaccharide. Some of the apparent exceptions are under investigation.

The following scheme of maltose decomposition in natural surface waters is proposed, this being additional to those already known .

$$\begin{tikzcd}[row sep=large] \text{Maltose} \arrow[d, "\textit{Pseudomonas}"] \\ \text{Maltobionate} \arrow[d, "\substack{\text{obligate aerobic micro-organisms}\\ \text{Enterobacteriaceae}}"] \\ \text{Glucose and gluconate} \end{tikzcd}$$

or

unidentified pathway.

The large number of strains observed suggests that this pathway for the metabolism of maltose may be quite important in Nature.

A full account of these and related results will be published elsewhere. We also hope to publish a preliminary investigation of the enzymatic mechanism in the near future. We are indebted to Sandoz, Ltd. (Switzerland), for a generous gift of lactobionate.

Deoxyribonucleic Acid Content of Haploid and Diploid *Aspergillus* Conidia

In 1948, Boivin, Vendrely and Vendrely[1] suggested that the somatic nuclei of a vertebrate species may contain a fixed amount of deoxyribonucleic acid that is double the amount present in the germ cells. Since then, a considerable volume of evidence has been obtained to support this view[2,3]. Some apparent exceptions, such as rat liver, have been found, but these can be explained by the presence of nuclei with different degrees of 'ploidy'. The evidence is consistent with the view that in resting nuclei a specific amount of deoxyribonucleic acid is associated with each set of chromosomes[4].

In vertebrate tissues it is difficult to make sure that a tissue has a population of nuclei homogeneous in respect of the number of chromosome sets. Therefore we have thought it of use to investigate the deoxyribonucleic acid content of conidia of diploid and haploid strains of *Aspergillus nidulans*[5]. These conidia are uninucleate ; genetic and cytological evidence shows that in different strains the nuclei are either diploid or haploid, and in the conidia the nuclei are all uniformly in one stage, presumably the resting stage. The volumes of the diploid and haploid conidia are[5,6] in the ratio of 2 : 1.

Two haploid strains were used : the wild type (+, green conidia) and a mutant strain (w_3) with white conidia[7]. Two diploid strains heterozygous for known markers were prepared[8] : one with green conidia (w_3 lys/ad_3 y) and the other with white conidia (28-*a*). The latter strain was obtained through somatic recombination[5,8] from a green diploid (w_3 $paba_1$ bi_1/ad_3 y). Cultures were grown on a minimal agar medium containing glucose and mineral salts. The conidia were harvested in saline containing 0·1 per cent calzolene oil and were counted in a hæmocytometer. They were precipitated with 0·5 vol. 30 per cent trichloroacetic acid and extracted successively with 10 per cent trichloroacetic acid (twice), acetone, ethanol, hot ethanol : chloroform 3 : 1, hot ethanol : ether 3 : 1 (twice) and ether. The dry powder obtained was extracted[9] with 5 per cent trichloroacetic acid at 90° for 15 min., and the deoxypentose in the extract was estimated by the diphenylamine method[10] with incubation at 37° for 18 hr. The results are expressed in terms of deoxyribonucleic acid phosphorus, the method having been calibrated with purified thymus deoxyribonucleic acid.

Strain	Deoxyribonucleic acid phosphorus (10^{-14} gm. per 10^{8} conidia)
Green haploid	4·04
Green diploid	9·39
White haploid	4·22
White diploid	7·75

Within the limits of the methods, these figures are consistent with a deoxyribonucleic acid ratio of 1 : 2 for the conidia from haploid and diploid strains.

Efficiency of Growth in *Mytilus edulis* and Two Gastropod Veligers

GROWTH efficiencies have been studied extensively in domestic animals and in some common laboratory animals[1]. Little is known, however, of the utilization of energy in the growth of lower animals. I have been able to show that marine invertebrates may have high growth efficiencies. Efficiency calculations were based on growth-rate and oxygen uptake in *Mytilus edulis* of different ages, and in veligers of two marine gastropods, *Littorina littorea* and *Nassa reticulata*. Rates of growth were calculated from average increases in length in Nature during known intervals of time. Data published by Thorson[2] were used in calculating growth-rates of veligers of *Littorina* and *Nassa* (from the Isefjord, Denmark) and of young metamorphosed *Mytilus* (from the Sound). I myself measured the growth of *Mytilus* veligers (from Isefjord). Data on growth of *Mytilus* during later stages were obtained from the Pacific off La Jolla, California, where Coe[3] measured the average increment in length of different age- and size-groups during August–November while maximum growth is taking place. Lengths were first converted into total nitrogen content using the relationship found by Zeuthen[4] (and unpublished results of Dr. Zeuthen). Then total organic matter was computed, assuming a nitrogen content of 8 per cent of the dry organic matter. Rates of oxygen uptake were obtained from Zeuthen[4]. The oxygen values were converted into organic matter by assuming that 1·2 litres of oxygen is equivalent to 1 gm. of organic matter.

	Length (mm.)	Nitrogen content (γ-nitrogen)	Daily increase in organic matter (per cent)	Daily combustion of organic matter (per cent)	Gross efficiency of growth (per cent)
Mytilus edulis veliger	0·09–0·26	0·003–0·07	11·2	4·2	73
Mytilus edulis metamorphosed	0·35–6·0	0·2–100	14·4	2·8	84
	11·0–22·8	580–2,900	5·7	1·8	76
	21·0–32·1	2,500–7,000	3·4	1·5	69
	31·0–40·9	6,500–12,000	2·0	1·3	61
	40·9–49·0	12,000–18,500	1·4	1·2	54
	51·0–56·9	21,000–27,000	0·8	1·0	44
	61·0–63·8	32,000–36,000	0·4	1·0	29
	90·0–90·8	82,000–84,000	0·1	0·8	11
Littorina littorea veliger	0·20–0·38	0·02–0·22	9·0	5·4	62
Nassa reticulata veliger	0·30–0·56	0·13–0·63	9·3	5·4	63

From the accompanying table it is seen that the efficiency of growth is of the same order in veligers of *Mytilus*, *Littorina* and *Nassa*. Furthermore, the efficiency of growth in *Mytilus* does not significantly change on metamorphosis. Owing to the heterogeneity of the material the increase in efficiency indicated in the table is probably not significant. A pronounced decrease in efficiency starts at a length of about 30 mm., when the growth-rate drops to about 2 per cent daily. Harvey[5] calculated that the efficiency of growth in the marine copepod *Calanus finmarchicus* was about 70 per cent. The growth efficiencies in *Calanus*, *Littorina*, *Nassa* and *Mytilus*, up to a length of about 50 mm., fall close to the values found in embryos. The gross efficiencies of growth of embryos for the hen, frog, fish and silkworm are 62, 51, 59 and 65 per cent, respectively (Brody[1], pp. 43–44). Maximum efficiencies of postnatal growth are generally found to be lower than in these marine invertebrates ; for example, 20–40 per cent in pig, trout and cockroach[6].

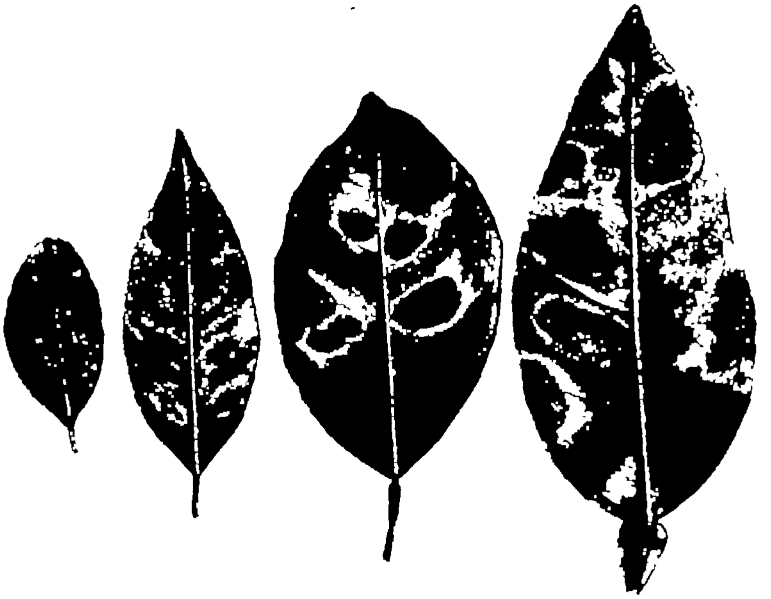
Molybdenum Deficiency in Florida Citrus

INVESTIGATIONS at this Station have disclosed that molybdenum deficiency is found in citrus trees throughout the citrus-growing area of Florida. The symptom of this deficiency has been called yellow spot since it was first described by Floyd[1] in 1908. Yellow spot has also been reported in citrus on the Isle of Pines[2]. Repeated studies[3] failed to demonstrate that it was due to an infectious fungus, bacterium or virus. It is known to occur on practically all kinds of citrus ; but the rootstock greatly affects the extent



Molybdenum deficiency of citrus leaves. Left to right leaves from Temple orange, tangerine, orange and grapefruit

to which the tree is injured. Trees on grapefruit rootstock are much more seriously affected than are trees on other rootstocks. This is one of the reasons why grapefruit has not been widely used as a rootstock in Florida.

Molybdenum deficiency in citrus appears first as water-soaked areas in leaves in the early spring. In the summer, these areas develop into large interveinal yellow spots with gum on the lower leaf surfaces (see photograph). Badly affected leaves eventually drop, and in extreme deficiency the trees become almost completely defoliated during the winter.

Molybdenum foliage sprays caused the yellow spot leaves to become green within three to four weeks after application. Some response was obtained when as little as 0·1 gm. of sodium molybdate was applied per tree. The lowest amount which gave a satisfactory response was 0·1 ounce per tree applied as a spray in 10 gallons of water. Equivalent amounts of ammonium molybdate have been equally as effective as the sodium salt. When 1 gallon of a solution containing 1 gm. sodium molybdate was injected under pressure into the trunk of a yellow spot tree, using an apparatus similar to that described by Southwick[4], the leaves became completely green within ten days.

The amount of molybdenum required by citrus is very small. Vanselow and Datta[5] in greenhouse studies found that molybdenum deficiency showed up in lemon trees in which the dried leaves analysed spectrographically contained 0·02–0·03 p.p.m. molybdenum. Chemical analyses made at this Station showed that the molybdenum content of yellow spot leaves from grapefruit and orange trees varied from 0·03 to 0·08 p.p.m. The molybdenum content of leaves from nearby green trees was found to be slightly higher in each instance. Samples of leaves taken from two yellow spot trees three months after soil applications of 1 gm. and 1 ounce of sodium molybdate were made showed the leaves contained 0·05 and 0·08 p.p.m. of molybdenum respectively. There was no noticeable greening of the leaves six months after the soil application.

Molybdenum sprayed on trees did not appear to be readily translocated. When the lower halves of grapefruit trees were sprayed with 1 ounce of sodium molybdate, leaves that were covered with the spray became green whereas those in the tops of the trees remained yellow and eventually dropped.

The total molybdenum content of Florida citrus soils has been found to be very low, ranging from 0·20 to 0·40 p.p.m. Water extractions were made on a large group of Florida soils and the amount of soluble molybdenum was found to be less than 0·001 p.p.m.

Studies[6] have shown that the amount of molybdenum taken up by plants increases with increasing *p*H of the soil. Grapefruit trees in plots at the Citrus Experiment Station growing on soil having a *p*H of 4·2 were severely affected with yellow spot, which caused almost complete defoliation of the trees. Chemical analysis of the leaves indicated they contained 0·03 p.p.m. molybdenum. Trees were green on adjacent plots where the soil had been limed to *p*H 5·6. The molybdenum content of leaves from these plots was found to be 0·06 p.p.m.

This is believed to be the first time that symptoms on trees growing in soil have been identified as due to molybdenum deficiency.

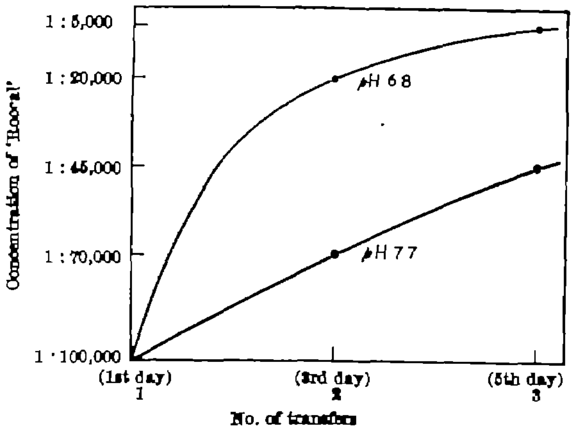
Factors Governing the Adaptation of Bacteria against Quaternaries

CHAPLIN has shown[1] that, contrary to a view current until then[2], it is possible to increase the resistance of certain Gram-negative bacteria to some quaternaries such as the cationic detergent 'Roccal' (alkyldimethylbenzyl ammonium chloride).

Using a sensitive strain of *Serratia marcescens* (obtained through the courtesy of Dr. C. E. Chaplin), we were able also to grow cultures resistant to higher concentrations of 'Roccal'. The experiments involved three direct transfers, namely, from a 1 : 100,000 dilution of 'Roccal' in nutrient broth containing 0·5 per cent 'Trypton' and of 'Peptone Difco', to one of 1 : 20,000 and then to one of 1 : 5,000; the *p*H of the media was found to be ~ 6·8 but varied slightly with the amount of 'Roccal' used. However, the bacteria adapted in this way did not survive when transferred to a nutrient broth containing



'Roccal' of a concentration of 1 : 5,000 at a pH of 7·4, but they survived at this pH in the absence of the quaternary.

When the above experiments were repeated under slightly alkaline environmental conditions (pH 7·7), the same dependence upon pH was found, because we were able to increase the resistance through three direct transfers from 1 : 100,000 to only 1 : 45,000, corresponding to a 2·2-fold higher concentration of 'Roccal' instead of the 20-fold reached when the pH was on the acid side; since we were mainly interested in the dependence on pH and not in the extent of the adaptation possible, we did not consider it necessary to carry out a greater number of transfers. In both experiments there is a maximum concentration for each transfer above which there is no survival. These concentrations are those used in our experiments and shown in the graph.

The results indicate that the adaptation is dependent on the pH of the medium, just as the bactericidal activity is. The bactericidal activity of a cationic compound is known to be enhanced by a rise in pH and to be diminished by a lowering of pH[3]. The rule has been shown to govern the affinity of a cationic compound for wool, and formed part of a general relationship found to hold between the bactericidal activity of a compound and its affinity for wool[4].

Quaternaries have a higher bactericidal activity against Gram-positive bacteria than against Gram-negative[2,5] bacteria. We have shown that such compounds, as exemplified by 'Bradosol' (phenoxyethyldimethyldodecyl ammonium bromide), have a higher affinity for a degraded wool, which we have taken to simulate the behaviour of Gram-positive bacteria, than for intact wool, the model for Gram-negative bacteria[6]. We conclude from this that the bactericidal activity of a substance is largely dependent on its affinity for that part of the bacteria (presumably cytoplasmic membrane) the behaviour of which is simulated by wool. It follows from this hypothesis that any factor which alters the affinity of a bactericidal agent for bacteria will affect the bactericidal activity in the same direction[7]. On this basis the results of our adaptation experiments become readily understandable. Since a rise in pH will increase the affinity of cationic substances, the bactericidal activity will increase, and it will require, therefore, a lower concentration of the cationic substance to produce the same effect as shown in the graph and further supported by the results in the accompanying table.

BACTERICIDAL ACTIVITY OF 'ROCCAL' AGAINST *S. marcescens* AFTER 24-HR. CONTACT IN NUTRIENT BROTH, AT DIFFERENT pH'S

Concentration of 'Roccal' in nutrient broth	pH 6·8	pH 7·4	pH 7 8
1 : 325,000	–	–	–
1 : 250,000	–	–	–
1 : 175,000	–	–	–
1 : 100,000	–	–	+
1 : 70,000	–	+	+
1 : 45,000	+	+	+
1 : 20,000	+	+	+
1 : 10,000	+	+	+
1 : 5,000	+	+	+

+, indicates activity*; –, indicates absence of activity.

* A reinoculation into fresh media was made to confirm that we were dealing really with a bactericidal action and not a bacteriostatic one.

A similar explanation can be used to show why Chaplin[1] was unable to render a Gram-positive organism resistant to quaternaries. Such compounds have a much higher affinity for Gram-positive than for Gram-negative bacteria, and therefore a much lower concentration of the compound would be required to enable the production of a resistant strain. In all probability, under the conditions of Chaplin's experiments, the concentration was always too high.

We acknowledge the gift of 'Roccal', supplied by Winthrop-Stearn, Inc., Windsor, Ontario.

Distribution of Dextran in the Tissues of Rabbits

THE increasing use of dextran solutions as plasma substitutes has made the problem of the fate in the organism of the injected polysaccharide a very important question. Several studies on this problem have been carried out by means of chemical and serological methods of determination of dextran in extracts of tissues[1], and a few histological investigations are recorded in the literature. The methods used in these studies are, however, inadequate, as they do not allow any conclusions to be drawn as to the nature of the deposits found in the tissues after injection of dextran.

It has been demonstrated by several investigators that a considerable part (about 25 per cent) of the dextran injected is excreted through the kidneys within a few hours. Others have suggested that a portion is eliminated by the intestinal tract[2]. But what becomes of the remaining dextran that slowly disappears from the blood without being detected either in the urine or in the faeces? Some authors postulate a breakdown of the polysaccharide to glucose units, which are metabolized in the body[3]. The localization of such processes is undetermined. A transient accumulation of dextran outside the vessels may be suggested, and the presence of dextran has been demonstrated in lymph nodes and spleen by the use of chemical and serological methods.

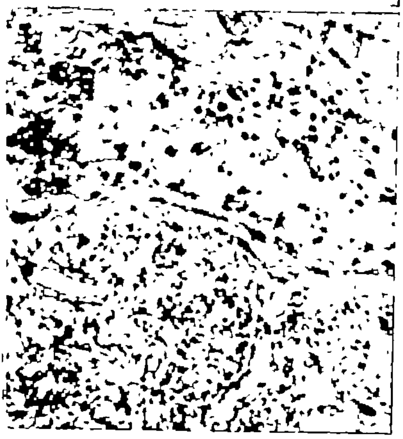

Fig. 1. Dextran inclusions in liver cells and Kupffer cells 48 hr. after injection of 'Macrodex'. Modified *PAS* reaction

Fig. 2. Polymorphonuclear leucocytes loaded with dextran 4 hr. after injection of 'Macrodex'. Modified *PAS* reaction

Fig. 3. Bone marrow with reticular cells loaded with dextran granules, 96 hr. after injection of 'Macrodex' intravenously. Modified *PAS* reaction

Fig. 4. Lymph node containing many macrophages filled up with dextran, 48 hr after administration of 'Macrodex' intravenously Modified *PAS* reaction

In order to follow the distribution of injected dextran ('Macrodex', Pharmacia) in various organs and tissues in rabbits, a series of histochemical investigations was started late in 1950. The determinations were based on the use of the periodic acid – leucofuchsin method. In order to assure a certain specificity to the reaction against dextran, the procedure described by Hotchkiss was somewhat modified. Furthermore, adjacent sections were treated with other oxidizing agents (chromic acid and permanganate), and with iodine and azur *A*. Thus it was possible to distinguish dextran from other polysaccharides in the sections. Detailed descriptions of the methods used are to be published elsewhere.

The present communication gives a short summary of the results of a series of histochemical investigations on 104 rabbits given 6 per cent 'Macrodex' parenterally in doses of 20 ml./kgm. body-weight. The organs and tissues of the animals were studied at intervals varying from 15 min. to 80 days after the administration of dextran. Liver, kidneys, spleen, lymph nodes, bone marrow, blood leucocytes, stomach, small intestine, thymus, adrenals, omentum and skin were examined.

Kidneys. The passage of the low-molecular part of the 'Macrodex' through the glomerulus and nephron during the first few hours after injection was well demonstrated in the sections. A small, transient deposition of dextran granules in the cells of the convoluted (proximal and distal) tubules was noted within the first twelve hours. No traces of dextran were visible in the tubular epithelium 48 hr. after administration.

Liver. The uptake of dextran by the liver cells was visible about 24 hr. after injection of 'Macrodex'. Some of the livers studied were deprived of most of their ordinary glycogen content by starving the animals for 24 hr. before autopsy. The dextran granules deposited in the liver cells were of uniform size, and scattered over the whole area of the cell without forming any floccules like glycogen (Fig. 1). Dextran inclusions were visible up to three days after administration. No dextran was observed in the bile ducts.

Blood leucocytes. An accumulation of dextran occurs very rapidly in the polymorphonuclear leucocytes. Within 15 min. of intraperitoneal or intravenous injection of 'Macrodex', a great many granulocytes were seen to be packed with dextran granules. The number of leucocytes with dextran inclusions was at a maximum 3–4 hr. after administration. At this time such cells are seen everywhere in the small vessels and in loose connective tissue (Fig. 2). In the spleen, dextran-loaded leucocytes are retained for several days. The histochemical properties of the dextran granules in the leucocytes differ from those observed with dextran *in vitro*. This may be due to a change in the chemical structure of the substance due to some enzymatic attack on the dextran molecule.

Reticulo-endothelial system. The spleen, lymph nodes, bone marrow and the Kupffer cells of the liver were studied as being important parts of the reticulo-endothelial system. The uptake of dextran by reticulo-endothelial cells was similar in all the organs and tissues studied. A moderate amount of the polysaccharide was visible within the cells about 12 hr. after intravenous injection of 'Macrodex'. The accumulation of dextran increased and showed a definite peak 48–96 hr. after administration. Especially in the bone marrow and lymph nodes, a great number of reticular cells and macrophages completely filled with dextran granules was visible (Figs. 3 and 4). Twelve days later, it was still possible to see a moderate number of dextran-loaded reticulo-endothelial cells in the bone marrow and lymph nodes. Thirty days after the injection of 'Macrodex', the reticulo-endothelial cells did not differ from those in the controls.

These observations suggest that the liver cells, the polymorphonuclear leucocytes, and the reticulo-endothelial cells, all of which are known to be enzymatically very active, play a part in breaking down dextran into units that can be utilized by the body or which can be easily eliminated from the organism. An interesting problem in this connexion is the effect of the accumulated dextran on the various physiological properties of the reticulo-endothelial system. Work on this subject is in progress in our laboratories.

Detailed reports on the results briefly outlined here will appear elsewhere.

Airborne Dispersal of *Phytophthora palmivora*, causing Black-Pod Disease of *Theobroma cacao*

AT the 1951 Cocoa Conference, Mr. G. F. Bowman, chief of the American Cacao Research Centre, Turrialba[1], referred to work by Salazar[2] which shows that the sporangia of *P. palmivora* are almost certainly not airborne, except in drops of water. Contrary evidence was not apparently produced at the Conference; therefore it is desirable to direct attention to certain observations in Nigeria which indicate that *P. palmivora* sporangia may be airborne and that infection apparently results thereby. In this respect, the species in question would appear to be comparable with *P. infestans* in temperate regions, the airborne dispersion of which has been discussed by Gregory[3] and by Van der Plank[4]. It seems necessary to postulate long-distance dispersal to explain the epidemiology of black-pod disease. Observations have therefore been made to test this hypothesis, and also to determine whether free moisture is essential for take-off and dispersal of sporangia in Nigeria.

Sporangia have been observed on 'Vaselined' disks of 'Cellophane' (3 mm. diameter), mounted on pins above the surface of an infected pod. The arrangement was generally such that the disk was facing the sporangia and parallel with the pod surface. The distance between the disk and the pod varied from approximately 5 mm. to about 20 mm. Six or more disks per pod were exposed for 12-hr. periods (7 a.m.–7 p.m. and 7 p.m.–7 a.m.). The maximum mean number of sporangia found per disk was 2·3, but generally the mean number was less than one per disk. Sporangia were caught on disks when free moisture was apparently absent during the exposure period. It should be noted in this connexion that Ashby[5] stated regarding *P. palmivora* in culture that "the sporangia when mature fall away from the sporangiophores by natural abscission . . .". This observation lends support to the experiments now described, which indicate that take-off of sporangia can occur without the assistance of water.

It is possible that Salazar's[2] failure to catch sporangia on plates may have been due to the relative inefficiency of large 'traps', which has been established by Gregory[3]. Small disks have been used in Nigeria because they are likely to be relatively efficient under the conditions of low wind velocity ($\frac{1}{4}$–1 m.p.h.), which prevail locally[7]. Having established the possibility of air dispersion of sporangia, it is necessary to ascertain whether the occurrence of the disease is in conformity with this finding.

Van der Plank[4] has described a procedure which is suitable for the examination of black-pod disease distribution in cacao fields, by observing the number of doublets (pairs of affected trees) in sequences of trees. In this connexion, it is convenient to describe a tree as 'diseased' when it carries one or more affected pods, as opposed to a 'healthy tree' carrying only healthy pods. Results from observations made in the same field on two occasions are summarized below.

Table 1. INCIDENCE OF DOUBLETS OF DISEASED TREES IN A CACAO FIELD

Date	No. of trees observed (healthy + diseased)	No. of diseased trees	No of doublets		Difference (observed − expected)	Standard error ±
			Observed	Expected		
29/5/50	451	55	7	6·6	0·4	2·57
10/7/50	303	244	207	195·7	11·3	13·99

Table 1 shows that the numbers of doublets observed exceed the numbers to be expected if diseased trees were distributed at random, but the differences are not significant, because they are less than their respective standard errors. Therefore such grouping as occurs, and which may be due to spread from neighbour to neighbour, could occur by chance ($P > 0·05$).

Further evidence of random dispersal has been obtained from observations on the spread of disease from a source consisting of a diseased tree with black-pods heaped around its base. The trees under observation were inspected every other day, and black-pods were recorded, removed and added to the heap.

Table 2. SPREAD OF BLACK-POD DISEASE FROM A SOURCE OF INFECTION

Distance from source (m.)	0–10	11–20	21–30	31–40	41–50	51–60	61–70	71–80	81–90
Diseased trees (per cent of total trees)	33	35	37	25	22	23	13	24	29
No. of diseased pods (per 100 trees)	69	85	98	45	48	34	23	43	44

There are indications of a decreasing gradient of infection from 0–70 m.; but from 71–90 m. there would appear to be an opposing gradient which may have been due to extraneous infection coming from some source beyond the observation area. The heap of pods occupied a space about 8 ft. in diameter, therefore it could not be properly considered as a point-source, which may partly account for the 'flatness' of the gradient in the interval 0–30 m. The results suggest random distribution from a central source, because an approximation to a straight line is obtained when the logarithm of the percentage of healthy trees is plotted against the number of diseased pods[6]. In connexion with the possible origins of extraneous infection, it is worth mentioning that there is no direct evidence under local conditions for the natural production of *P. palmivora* sporangia from alternative hosts or on parts of the living cacao tree except the pods. Sporangia have been observed on chupons (vertical stems) following artificial inoculation.

It has been shown that there is evidence for horizontal dispersion of black-pod disease in a random manner, such as would be expected for an airborne disease. There is also evidence for vertical spread in such a way that healthy pods become infected from diseased pods several feet below. It is probable that sporangia are commonly dispersed from infected pods in splash droplets, but there is evidence that take-off can occur in 'dry' air; it appears that sporangia may be airborne over considerable distances.

Phytophthora palmivora can readily infect healthy pods through wounds; hence there is a possibility that some pod infection may be associated with insect damage. Most of the pod damage by insects in Nigeria is ascribed to *Helopeltis* sp., but casual observations indicate that it is only exceptionally that black-pod infection is associated with such insect punctures.

Black-pod disease studies are continuing and detailed results will be published elsewhere. I am greatly indebted to Dr. P. H. Gregory, Rothamsted Experimental Station, for his advice and suggestions adopted in the preparation of this communication, which is published with the permission of Mr. A. G. Beattie, Inspector-General of Agriculture, Nigeria.

Gilbert of Colchester and Wingfield House

DR. WILLIAM GILBERT, who wrote the celebrated treatise, "De Magnete", and who was physician to Queen Elizabeth I and president of the College of Physicians, lived and worked in London in a "capital messuage or mansion" called Wingfield House. There, in a bachelor establishment, he gathered about himself a group of students of the new learning and developed the scientific method of inductive reasoning, his "new sort of philosophising", which he applied to experiments on magnetism and static electricity.

Wingfield House was in St. Peter's Hill, in the parish of St. Peter, Paul's Wharf. So much is apparent from published records and has already been noticed in accounts of Gilbert's life. It seems worth while to identify this interesting site more closely, however, for it was in Wingfield House that the seed of modern science in England germinated and bore its first fruit.

The earliest known reference to Wingfield House is in an indenture executed in 1519[1]. It is not clear how or when the house came into Gilbert's possession, though the fact that his stepmother was a Wingfield provides a clue. However, the successive ownership of the property after Gilbert's death in 1603 can be traced through his will[2] and through various deeds of conveyance[3,4] until the time of the Great Fire of 1666, when the house was destroyed. Collation of entries in the manuscript survey of building sites in London after the Great Fire[5] with Ogilby and Morgan's map of London published in 1677 shows that Wingfield House stood opposite the northern end of the College of Arms, almost exactly in the middle of the east side of the remnant of St. Peter's Hill that runs between Knightrider Street and Queen Victoria Street.

It appears from the deeds that the front of the house was 36 ft. wide, and that the site extended back about 100 ft. Some years after Gilbert died, part of Wingfield House was sold to "the Master, Wardens and Cominalty of the Mystery or Art of Upholders"—that is, the livery company of Upholders or Upholsterers. The indenture[4] that defines the partition of the property describes the house at some length. There was a paved yard near the middle of the site between a fore part and a rear part of the building, the two parts being connected by the kitchen, which presumably flanked the yard. There was probably also another yard or garden at the back.

The eastern side of St. Peter's Hill was devastated again during the Second World War. The remains of a wall that can be seen running east from the street may well mark the northern boundary of the site of Wingfield House.

Cooling Bath for Cytological Investigations

THE disadvantage of liquid air[1] as a cooling bath for the rapid quenching necessary in freezing and drying for cytological purposes was recognized by Hoerr[2] as the formation of a vapour coat of low thermal conductivity around the specimen. He introduced isopentane for this purpose as a liquid of high boiling point which did not vaporize around the piece of tissue. Isopentane cannot be cooled below its melting point, – 160° C., and near this temperature is a thick liquid which cannot be stirred efficiently. In a search for a better bath liquid it has been found that propane has several advantages. It can be cooled to – 190° C. and is still very fluid near its melting point. It is easily obtainable as 'Propagas' (B.O.C.)[3]. Both isopentane and propane have to be cooled with liquid nitrogen, because of the fire and explosion hazard with liquid air or oxygen.

With the increasing use of freezing and drying by histologists and cytologists, it is of interest to report that a non-inflammable and non-toxic cooling bath can be made by condensing dichloro-difluoromethane in a tube cooled by liquid air. This material is easily obtained as 'Arcton 6' (I.C.I.) and has a melting point of – 158° C. It is denser than either of the hydrocarbons, and the pieces of tissue float on the surface after quenching, allowing easy recovery from the bath. The possible use of such a bath was discussed at the Bristol meeting of the cytochemistry commission of the International Society of Cell Biology in July 1951.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 27

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Impact of Television on Sound Broadcasting" (to be opened by Mr. G. Parr).

Chemical Society, Oxford Section (in the Physical Chemistry Laboratory, South Parks Road, Oxford), at 8.15 p.m.—Prof. Alexander Haddow: "Carcinogenesis" (Alembic Club Lecture) (All Fellows are invited.)

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Capt. John Giaever and Mr. G. de Q. Robin "International Expedition to Antarctica".

Tuesday, October 28

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. Colin Smith: "Renan and Science".*

Iron and Steel Institute (joint meeting with the British Iron and Steel Research Association, at 4 Grosvenor Gardens, London, S.W.1), at 2 p.m.—Discussion on "The Corrosion of Steel under Phosphate Coatings and Protective Finishes".

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 2.30 p.m.—Sir Martin Roseveare: "The School and the Health of the Community".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. Bernard W. Bradford: "Physical Chemistry in the Chemical Industry". (Further Lecture on November 4.)

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Mr. D. O. Walter: "The Design of Sliding Contact Assemblies in Instrument Applications".

Tuesday, October 28—Wednesday, October 29

Institute of Fuel (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 10 a.m. each day.—Conference on "A Special Study of Ash and Clinker in Industry".

Wednesday, October 29

Physical Society (at the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Presentation of the Planck Medal to Prof. P. A. M. Dirac by Prof. M. von Laue.

Royal Statistical Society, Research Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. F. J. Anscombe: "Sequential Estimation".

Institution of Electrical Engineers, Supply Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. C. M. Cook: Chairman's Address.

Thursday, October 30

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Miss Pauline Whitby: "Animal Food".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Harold Spencer Jones, F.R.S.: "The Masses of the Sun, Planets and Stars". (Further Lectures on November 6 and 13.)

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Dr. E. W. Still: "Temperature Control for Pressure Cabin Jet Aircraft".

Friday, October 31

Royal Meteorological Society, Scottish Centre (in the Department of Natural Philosophy, The University, Drummond Street, Edinburgh), at 5 p.m.—Prof. P. A. Sheppard: "Atmospheric Turbulence and the General Circulation".

Bedson Club (in Lecture Theatre I, Chemistry Building, King's College, Newcastle-upon-Tyne), at 5.30 p.m.—Prof. C. W. Davies: "Ion Association" (87th Bedson Lecture).

Manchester Statistical Society, Industrial Group (at the Portico Library, Mosley Street, Manchester), at 6 p.m.—Mr. R. F. H. Banister: "What Management Expects of Statisticians".

North-East Coast Institution of Engineers and Shipbuilders (at the Literary and Philosophical Society, Westgate Road, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. Claude Seippel: "From Stodola to Modern Turbine Engineering" (Parsons Memorial Lecture).

Royal Institute of Chemistry, London and South-Eastern Counties Section (joint meeting with the University Chemical Society, in the Chemical Laboratory, Pembroke Street, Cambridge), at 8.15 p.m.—Dr. T. C. J. Ovenston: "By-Ways in Absorption Spectrophotometry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Morris W. Travers, F.R.S.: "Sir William Ramsay".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant (Grade B) in Biology—The Principal, Acton Technical College, High Street, Acton, London, W.3 (November 1).

Research Assistant at the Plastic Surgery Centre, for work in connexion with the application of radioactive isotopes to clinical research—The Group Secretary, Odstock Hospital, Salisbury (November 1).

Teachers of Mathematics and Physics, Iraqi Ministry of Education, Baghdad—The Director, Personnel Department, British Council, 65 Davies Street, London, W.1, quoting subject and 'Baghdad' (November 1).

Assistant Lecturer in Electrical Engineering—The Registrar, College of Technology, Manchester 1 (November 3).

Chemist (Scientific Officer grade) (with suitable good honours degree and, preferably, some research experience) for research on the proteins and enzymes of milk—The Secretary, National Institute for Research in Dairying, Shinfield, Reading (November 8).

Plant Pathologists (with a four-year degree in botany, agricultural botany or agriculture, with at least one year's specialization in plant pathology), Southern Rhodesia Government—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (November 8).

Research Assistant (qualified in social anthropology or sociology and statistics) to engage in a community research project—The Registrar, The University, Leeds 2 (November 8).

Scientist (with a good honours degree in natural science (physics, chemistry or mathematics) preferably with experience in the study of dust and other industrial environmental problems) on the staff of the Director of Scientific Control at London headquarters, to co-ordinate and supervise environmental studies which are to be carried out at 20 or more selected collieries during the next 10 years as part of a field research on pneumoconiosis—The National Coal Board, Establishment (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/544 (November 10).

Textile Scientist (Senior Research Officer or Research Officer grade) in the Physics and Engineering Unit of the Wool Textile Research Laboratory, Sydney, to develop a programme of research into the physical properties of fibre assemblies or into the physical principles of textile processes—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 4010 (November 15).

Chair of Pharmacology at St. Bartholomew's Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 17).

Senior Lecturer in Botany (Plant Physiology) at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 1).

Lecturer in Civil Engineering at the University of Queensland—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 15).

Lecturer in Zoology at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 3).

Rutherford Scholarship for research in any branch of the natural sciences—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (February 15).

Assistant (with a degree in botany or natural science and some training in plant pathology) to the Chief Officer, and a Research Assistant (with a degree in botany or natural science), in the Official Seed Testing Station for England and Wales—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Assistant Lecturer in Chemistry—The Acting Registrar, University College, Exeter.

Geologist for service in the Antarctic with the Falkland Islands Dependencies Survey—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.33272.E.

Head of the Department of Chemical Technology, Indian Institute of Science, Bangalore—The Ministry of Labour and National Service (A.S.12), Almack House, 26 King Street, London, S.W.1, quoting A.12/1.31.E.

Librarian-Information Officer (with a science degree and, preferably, a working knowledge of French or German)—The Director, Fruit and Vegetable Canning and Quick Freezing Research Association, Campden, Glos.

Physical Chemist (Scientific Officer or Senior Scientific Officer grade) at a Ministry of Supply research establishment in South-West England, to lead a small group working upon a variety of research problems in physical chemistry—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.669/52A.

Research Assistant in the Department of Aeronautical Engineering, to aid and initiate researches in the study of noise from aircraft and jets—The Registrar, The University, Southampton.

Scientific Officer or Senior Scientific Officer, for an investigation on the soundness of iron castings—The British Cast Iron Research Association, Alvechurch, Birmingham.

Senior Plant Pathologist (with a good honours degree and considerable postgraduate research experience of virus diseases of trees and, if possible, of handling insect vectors) at the West African Cocoa Research Institute, Gold Coast—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. No. 63/86/01.

Senior Scientific Officer for chemical and technical investigations of plant and animal products, and assistance in preparation of memoranda, reports and replies to inquiries regarding their production, preparation and marketing (Ref. F. 666/52A), and a Scientific Officer to assist in the duties outlined above (Ref. F. 667/52A), at the Colonial Products Advisory Bureau (Plant and Animal), London, S.W.7—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

University Graduate or Postgraduate in Electrical or Mechanical Engineering, Physics or Mathematics (with at least three years experience in the application and use of gyroscopes in navigational instruments and the development of low wander rate gyros)—The National Research Council of Canada, Africa House, Kingsway, London, W.C.2, quoting Ref. No. 2908.

ACADEMIC FREEDOM IN THE MODERN STATE

THE appearance after an interval of two years of a new review of the activities of the Rockefeller Foundation[*] would in any event be of considerable interest, and especially as in this survey Mr. Chester Barnard attempts to re-assess the objectives of the Foundation and its position in the world. He is not content merely to describe the reorientation of the Foundation's activities and its new objectives, but also endeavours to relate them to the general needs and problems of our time. This analysis is of the more interest in view of some comments on the position of such voluntary bodies which are made in the seventh report from the Nuffield Foundation[†], published almost simultaneously. Together the two reports give an encouraging picture both of the way in which such voluntary bodies are able to foster creative work and also of their indispensability if human society is to remain healthy and flexible in an age when research itself is increasingly dependent on public, or rather State, support.

Mr. Barnard points out that the resources of the Rockefeller Foundation are limited indeed in the face of the myriad wants of mankind, and because of this disparity the Foundation can select for support only those wants which represent critical needs and which provide opportunities for service in fields that are at the very basis of human well-being. In discharge of that heavy responsibility of selecting the most appropriate projects, the trustees and officers of the Foundation are entitled to draw some encouragement from the results which have flowed from some almost trifling grants. Mr. Barnard refers to the way in which the Montreal Neurological Institute, to which the Foundation has already appropriated nearly one and a half million dollars, has arisen from a grant of 2,784 dollars made twenty-five years ago to Dr. W. Penfield for a fellowship in neurosurgical research at McGill University.

Mr. Barnard uses this grant to illustrate the potency of the comparatively small grants—at least when measured against the resources of the State—which independent and voluntary organizations can make for research. Nevertheless, he emphasizes that the principle of adequacy is the correct yardstick to apply in any decision regarding the magnitude of a grant, and his discussion of this point vividly recalls some remarks of Sir Henry Tizard in his Messel Memorial Lecture. This illustration is even more significant, however, in its demonstration of the value of the voluntary organization with its freedom to experiment in fields where it would be difficult for the State to commit its own resources. The Rockefeller Foundation, as Mr. Barnard sees it, must work, irrespective of the magnitude of the project which is to be undertaken or of the size of the grant which is to finance it, with small groups, such as university departments, laboratory teams and individuals, who are both technically competent and intellectually free.

---

[*] The Rockefeller Foundation: a Review for 1950 and 1951. By Chester I. Barnard. Pp. 126. (New York: Rockefeller Foundation, 1952.)

[†] Nuffield Foundation. Report for the Year ending 31 March 1952. Pp. 162. (London: Nuffield Foundation. 1952.)

From this point of view Mr. Barnard shows concern at the increase of restraints on individual and group freedoms imposed in the interests of national security. The code of morals prevalent in Western society, in his view, rests on the twin pillars of the freedom and the responsibility of the individual. Recognizing the necessity for security and the difficulties of attaining it, he discusses what adjustment can be made that will preserve the life of the mind without endangering national security.

Mr. Barnard thinks that the sense of responsibility to institutional and public interest within the academic fraternity in the United States is not, on the whole, as mature as is desirable. With some qualification, that is possibly true of academic circles in Great Britain also, and it will be remembered that Prof. A. V. Hill made a similar comment in his presidential address to the British Association. Nevertheless, free discussion in the academic world is of increasing importance when so many activities in other fields are largely and necessarily subject to formal co-ordination and to central direction.

The Rockefeller Foundation, Mr. Barnard points out, endorses the view that only the free mind is capable of really productive intellectual work, either in research or in teaching, and that the man or woman who has an ideological axe to grind is conspicuously less successful as a contributor of knowledge than one who is free of such a restriction. The two personal criteria by which the Foundation judges eligibility for grants and fellowships are technical competence and integrity as a scholar. The first requisite for intellectual integrity is an open mind; once a man becomes a partisan in his search, and accepts the dictation of external authority as to the interpretation of the phenomena he observes, he ceases to be a scholar.

That still needs saying, and Mr. Barnard's further contention that those who sacrifice their freedom to a party line thereby disqualify themselves for research, and automatically exclude themselves from the immunities granted by society to the scholar in exchange for his dedication of himself to the search for truth, points the way towards a solution of the problem of freedom and loyalty and responsibility. The view taken by Mr. Barnard is, in fact, thoroughly realistic. Strongly as he argues that freedom to inquire, to observe, to theorize, to exchange ideas and experiences and to criticize, is essential to fundamental research and for creative work of any kind, he recognizes too that in some areas of research, where national security is involved, the traditional liberty of the scholar is subject to restriction in the interests of the nation and society. It cannot be granted as an inalienable right, and the scientific man who wishes to work in such areas must accept the restriction as an unavoidable evil. If he feels that he cannot fulfil his responsibility in research unless he can communicate his findings freely with other scholars and share their discoveries, a man of science should withdraw and work in another field where such secrecy considerations are not over-riding. He can claim no right to set his own judgment as to the necessity of free communication above the judgment of those who may be no less concerned with scientific advance but who are responsible also for maintaining national security. Moreover, to withdraw, as Prof. Hill very clearly indicated, is probably the surest way of emphasizing to the nation and to society the high cost of secrecy measures, and the way in which such measures impede both scientific discovery and technical development.

In this review, Mr. Barnard sounds a warning that has been given before in the Rockefeller Foundation reports; but while it is clear that the Foundation would be seriously concerned at any considerable extension of secrecy areas, the purpose of the present warning may equally be to give notice of the Foundation's concern with intellectual integrity, and its desire to foster a keener sense of public responsibility on the part of the scientific men and other scholars. The issue of academic freedom is also raised by the Nuffield Foundation in its seventh report, but from a rather different point of view. Although the fears expressed in its previous report of a sudden setback to the development of university work in Britain through a contraction of government spending have not been realized, the Foundation is still somewhat exercised as to the possible effects the increasing dependence of the universities upon public money may have on the traditional independence of academic work and the freedom of universities to manage their own affairs.

Some three-quarters of the total income of the universities of Britain will presently be derived from government sources, and while for the moment the universities will only have to face such restrictions on their activities as may be imposed by rising costs, the Nuffield Foundation is somewhat concerned at a passage in the Fifth Report of the Select Committee on Estimates for the Session 1951–52. That report, which subjected to careful analysis the grant-in-aid of universities and colleges from the point of view of public accountability, provided a striking indication of the effectiveness of the University Grants Committee system. The Select Committee was satisfied that the arrangement successfully harmonized academic freedom with proper control over the expenditure of public funds, and at the same time urged the desirability of securing the maximum contribution from private benefaction and local support.

It is on this question of further revenue from private gifts and endowments that the Nuffield Foundation is critical. The Select Committee noted that there was evidence of the same antipathy on the part of universities towards ear-marking by private benefactors as towards ear-marking by the Exchequer. Private benefactions, indeed, are apt to be even more restrictive than State ear-marked grants, and 54 per cent of total endowments are given for particular purposes. The Estimates Committee made no comment on this point; but the Nuffield Foundation takes up strongly the plea that private benefactions should not be tied by the donors to the creation of some particular facilities or the promotion of special projects.

Universities naturally prefer to be left unfettered in deciding the best use for such private donations, so that they can experiment with new developments or test out novel ideas; and the Foundation is fully mindful of the needs and circumstances of universities as centres of teaching at the highest level and of most of the research which advances knowledge. In previous reports, the Foundation has stressed the importance to-day of the comparatively much smaller but alternative resources which private funds can offer in support of activities so speculative as research. In the present report, the Foundation makes a spirited defence of its practice of making grants to universities for particular rather than for general purposes.

In doing so, the Nuffield Foundation could have drawn upon the experience of the Rockefeller Foundation as well as on its own. Both bodies, in seeking to use their endowments to foster those advances in knowledge from which human welfare stands ultimately to gain, have been concerned primarily with the exceptional men upon whom those advances depend. Both have made their grants more for special individuals than for special projects, and the Nuffield Foundation can claim with reason that it has been privileged on occasion, by enlarging the resources available at a university, without imposing restrictive conditions, to enlarge also the freedom both of the exceptional individual and of his institution. The object of any Nuffield Foundation grant is simply to give the individual able worker the means for carrying forward experiment and knowledge in the way which, because it suits him, is likely best to serve his subject.

The example cited by the Foundation in this report to demonstrate the decisive value of private benefactions for a specific purpose is the personal grant from Lord Nuffield in 1942 and grants from the Nuffield Provincial Hospitals Trust in 1943, which prevented the dispersion of Sir Howard Florey's team of research workers on penicillin. The instance cited by Mr. Barnard of the fellowship for neurological research equally establishes the value of the specific grant; and on the evidence of these two reports alone there can be no doubt as to the contribution to scientific advance which the voluntary association can make by means of its grants and endowments for specific purposes.

Implicit in both these reports is the belief in wise and responsible selection of individuals and projects. No objection has been raised to the acceptance of ear-marked grants or endowments from bodies of the standing of the Nuffield Foundation or the Rockefeller Foundation, with their established tradition of wise selection and public responsibility. It can equally be agreed that the fellowship schemes like those of Imperial Chemical Industries, Ltd., where full freedom of choice is allowed within whole scientific disciplines, are also a means for encouraging the emergence of the exceptional investigator. It would be unwise, however, to assume that every private benefactor will possess either the same tolerance or keen sense of public responsibility. Save where the repute and standing of the benefactor in these respects are beyond dispute, the universities are wise to prefer the uncommitted grant or endowment. Bodies like the Nuffield Foundation and the Rockefeller Foundation have an essential part to play in encouraging the development of backward or neglected fields. Great Britain could ill spare the effort which the Nuffield Foundation, for example, proposes to make during the next five years to encourage fundamental research in the United Kingdom in the biological and sociological fields, and to utilize special opportunities in other fields of medicine and science, as well as in old people's welfare and in the finance of biological and other research in the Commonwealth, particularly in the utilization of local resources.

But the Nuffield Foundation is well qualified to discuss the opportunities which exist or can be created for work of high standard in such fields. Its choice, in the ultimate resort, is made on the quality of the individual and is guided by lively contacts with academic thought and practice. The real issue for us to-day is to secure the continuance of such independent bodies, and provide the conditions by which such voluntary effort can continue to maintain the growing points and opportunities for experiment in society to which the State itself—directly or indirectly—can with difficulty, if at all, commit itself. Perhaps the most encouraging feature of the present report from the Nuffield Foundation is the indication it affords of the way the Foundation finds it possible to work, formally and informally, in co-operation not only with the universities but also with the major departments of State and the official research organizations, and to bring to the common task the flexibility, initiative and independence which mark the voluntary body.

FREEZING AND DRYING

Freezing and Drying

Report of a Symposium held in June 1951. Pp. 206. (London: Institute of Biology, 1952.) 15s.

THIS report contains all the papers read at a symposium at the Institute of Biology which was held in London during June 1951. In addition to the papers, the whole of the discussion which followed them has been included. The complete compendium is a most valuable contribution to this rapidly expanding subject.

The principle of freeze-drying is, of course, dependent upon the fact that frozen water has a significant vapour pressure, and even at − 20° C. this is equal to about 0·9441 mm. of mercury. Consequently, in a vacuum of a lower pressure than this, the frozen water will pass directly into vapour (that is, it will sublime) and can be removed from the system. Progressive removal of the water vapour so formed will eventually cause the drying of the tissue. Biological fluids and tissues kept at these low temperatures remain virtually inactive. Autolytic reactions do not take place, growth of micro-organisms is prevented and proteins are not denatured. Moreover, most enzyme activity of tissues and fluids frozen-dried in this way is maintained. The advantages of freeze-drying were, of course, made use of during the Second World War, when the production of large quantities of dried blood-plasma and penicillin were made possible by its use. A glance at the list of papers read at the symposium and recorded in this volume demonstrates the range of activities to which this technique is now applied.

First, there is a series of four papers on what can best be described as large-scale freeze-drying—that is, treatment of antibiotics and foodstuffs—by this method, and also discussions on methods of freeze-drying. A second section deals with effects of freeze-drying on the viability of cells and tissues. Here we have papers on mammalian skin, tumour tissues, spermatozoa, red blood cells and endocrine tissue.

A third section records the effects of freeze-drying on bacteria and viruses, and a fourth discusses the problems of tissue fixation by freezing and drying and its significance in histochemical and cytological studies. This latter problem was, in fact, first investigated by Altmann as long ago as 1890, but was neglected until it was more fully investigated and improved in the early 1930's by Isadore Gersh in the course of his studies for the degree of Ph.D. at the University of Chicago; Dr. Gersh himself read the opening paper in this section.

It can be seen that there are few biological activities—commercial, bacteriological, cytological, etc.—which are not affected by the development and further application of this new technique. This volume should therefore have a wide and ready sale.

As a record of the first symposium held by the newly formed Institute of Biology, the book augurs well for the future of the Institute's activities.

GEOFFREY H. BOURNE

HORMONES IN PLANTS AND INVERTEBRATES

The Action of Hormones in Plants and Invertebrates

Edited by Kenneth V. Thimann. (Reprinted, with additions and supplementary bibliographies, from 'The Hormones', Vol. 1.) Pp. viii+228. (New York: Academic Press, Inc., 1952.) 5.80 dollars.

THIS volume consists of four essays on the hormones of plants, insects and crustaceans, gathered together under one cover in the hope that their proximity might lead to the same sort of unification as has occurred in mammalian endocrinology. One is left with the impression that the realization of unity has been somewhat less than the anticipation. Although each of the essays possesses considerable intrinsic value to workers in the particular field discussed, there seems to be relatively little carry-over between the various groups. In fact, one is led to wonder whether the study of hormones has as yet been so significant a unifying force in biology as the editor believes. Aside from the universal occurrence of hormonal mechanisms of correlation and control in complicated organisms, one can think of no major generalizations to make. If other basic similarities do, in fact, exist, they need to be pointed out, for they are well hidden.

The four essays are "Plant Growth Hormones" and "Other Plant Hormones" by Prof. Kenneth V. Thimann of Harvard University, "Hormones in Insects" by Berta Scharrer of the University of Colorado, and "Hormones in Crustaceans" by Prof. Frank A. Brown, jun., of Northwestern University. They have been reprinted from Vol. 1 of "The Hormones" (1949), together with some additions to the text and supplementary bibliographies to bring them up to date as of late 1951. It is hoped that such supplementation will make complete revision unnecessary for some years to come.

Prof. Thimann's article on plant growth hormones is a skilful condensation and modernization of the kind of material originally presented in Went and Thimann's "Phytohormones". The result is a brief coherent survey of the state of our knowledge of the chemistry and physiology of the auxins up to five years ago. Because of the extremely rapid advances which are now being made in this field, parts of the auxin story are somewhat out of date, and the inclusion of the recent bibliography does not quite remedy the situation.

The chapter on "Other Plant Hormones" is especially welcome, since it summarizes much material not before integrated. One may find here authoritative discussions of the wound hormone, flower-forming hormones, vitamins which act as plant hormones, leaf growth-factors, calines and the hormones of fungi. Since relatively little important work has been done in these fields in the years since the article was originally written, it is as complete and up-to-date a review as one could hope to find.

The comparatively young field of invertebrate endocrinology has very recently produced a spate of interesting discoveries on hormonal regulatory effects in insects and crustaceans. Most of these hormones have been shown to exist by purely physiological and surgical means, and in only one instance, the formation of eye pigments in *Drosophila* and *Ephestia*, has the chemical nature of the hormone been definitely ascertained. Nevertheless, these studies hold great promise for an eventual rationalization of the complex problems of growth and morphogenesis, especially in the insects.

Dr. Scharrer discusses insect hormones under the following headings: (*a*) hormones controlling postembryonic development, (*b*) sex hormones, (*c*) hormones affecting pigmentation, and (*d*) "gene hormones", that is, hormones directly involved in the expression of a particular gene. Although distinct differences are shown to exist among various orders of the insects, it seems clear that in all groups there are hormones controlling larval growth, pupation and moulting. It also seems clear that an 'anti-differentiation factor' (the juvenile hormone of Wigglesworth) is present. In this respect, one can see a broad analogy with plants, in which there appears to be a growth versus sexual differentiation control by the interplay of auxin and florigen. The corpora allata, the centres of synthesis of the juvenility factor, may thus be regarded as analogous with the stem tip, in which the major share of auxin synthesis occurs; and the neuroglandular intercerebralis–cardiacum complex, which produces the growth and differentiation hormone, with the leaves which produce florigen. It would be interesting to know whether the production of the growth and development hormone in insects is as sensitive to environmental control as is the synthesis of florigen in plants.

In the Crustacea, discussed by Prof. Brown, no single hormone has yet been obtained in a pure state, but many are known to exist. As in the insects, they control colour-change, moulting and growth, sexual processes, and certain aspects of growth, development and metabolism. Some of these hormones have been hypothesized almost exclusively on the basis of observation, as in the effects of parasitic castration on secondary sexual characteristics. With others, especially hormones involving colour changes, a sound experimental basis for their existence has been laid. The account of the hormonal control of chromatophores by the sinus gland and central nervous organs is especially exciting.

The study of hormones in plants and invertebrates, which began less than thirty years ago, has already wrought a revolution in our understanding of the physiology of these types of organisms, and the increasing tempo of research augurs well for its future. This volume is a valuable chronicle of progress in a vigorously growing field, and it is hoped that it may aid in achieving the unity in biology to which Prof. Thimann dedicates it.

ARTHUR W. GALSTON

THE FULMAR POPULATION

The Fulmar

By James Fisher. (New Naturalist Series.) Pp. xv + 496 + 52 plates. (London and Glasgow: Wm. Collins, Sons and Co., Ltd., 1952.) 35*s.* net.

THE nucleus for the present work was the British Trust for Ornithology Inquiry into "The Breeding, Distribution, History and Population of the Fulmar (*Fulmarus glacialis*) in the British Isles", conducted by the author and George Waterston (*J. Animal Ecol.*, 10, 204; 1941). In the published paper the spread of the fulmar from one colony in 1874 to 269 colonies in 1939 was considered by the authors to be "due to a biological change which is not understood". As a plankton-eating arctic species the fulmar should have been retreating northwards with the shrinking of the ice-cap and the amelioration of the climate of the northern hemisphere—but, in fact, it was moving south at a great rate. They wrote: "Correlations may exist between the spread of the fulmar and its food, but it will be a Herculean task to discover them".

A simple solution was, however, discovered by Marchant and myself on our visit of nine days at Rockall in June 1948, when we became convinced that the fulmar's increase was related to the availability of the tons of fish offal which are thrown into the sea each hour of each day all the year round by the great fleets of deep-sea trawlers of the maritime nations of Western Europe. We saw up to five thousand fulmars at one moment devouring this offal, which was hosed over the side of the trawler after the gutting of each trawl-load of about a ton of fish every four hours day and night. As it is now known that the larger petrels are capable of long fasts and of flying great distances there is no reason why most of these fulmars at Rockall (or at any other trawling bank) should not be breeding birds from the nearest colonies between two and four hundred miles away. At least fifty thousand fulmars were present on the Rockall Bank during June 1948 (they could not have all been non-breeders), which is $2\frac{1}{2}$ per cent of Fisher's estimated world population of one million pairs of Atlantic fulmars. Once it had tasted offal in this form the individual fulmar would be likely to attend trawlers regularly and even become quite dependent on this (at present) unfailing and abundant food supply. Hence the rapid colonization by nesting sites along the Iceland–British Isles seaboard within a few hundred miles of the trawling grounds. Making use of this hypothesis, the author has investigated the northern fisheries as far back as the height of the whaling period of the seventeenth century. Whale-flensing provided an abundant, though only seasonal, supply of offal for the scavenging fulmar. His analysis shows a significant correlation: a slight increase in the number of fulmar colonies during two hundred years of whaling, a rapid increase with sixty years of deep-sea trawling; the increases taking place near the sites of these fisheries.

A short review cannot do justice to the excellence of this large monograph. Fisher shows how much of the breeding biology is yet unknown; the incubation period has not been accurately measured; and a theory of intermittent breeding is discredited. Field ornithologists especially will welcome his lucid presentation of the history of the distribution and increase of this remarkable petrel, gathered as it has been from the reading of more than 2,400 references. Disappointingly, none of these is listed in the monograph; but we are promised the bibliography later.

R. M. LOCKLEY

NEW LIGHT ON ALCHEMY

The Alchemists

Founders of Modern Chemistry. By Dr. F. Sherwood Taylor. Pp. x + 246. (London: William Heinemann, Ltd., 1951.) 12*s.* 6*d.* net.

DR. F. SHERWOOD TAYLOR'S book appeared very appositely just at the time of the recent exhibition of alchemical books at the Science Museum, South Kensington. It is apposite in another way also, for the modern trend in history pays much more attention than ever before to the growth of ideas, and it is from this point of view that Dr. Sherwood Taylor surveys his subject. The literature of alchemy is formidable, not only for sheer bulk but also for its complexity and often deliberate obscurity; many of its students have sooner or later become discouraged by vain attempts to thread their way through the labyrinth, and have indeed doubted whether, if it could be threaded, there would be anything worth discovering at the centre. One may, of course, investigate the alchemical *corpus* solely in order to assess the matter-of-fact chemical knowledge contained in it; but even this is not easy on account of the enigmatic nomenclature so generally favoured by the alchemists. Genuine practical chemistry is, however, only one facet of the alchemical crystal: the sparkle comes mainly from the numerous facets of doctrine. What Dr. Sherwood Taylor has set out to do, and what, in fact, he has succeeded in doing very well, is to examine alchemical doctrine to see if any coherence and continuity can be detected in it. He has the advantage of being a chemist versed not only in chemistry but also in theology, philosophy, and mysticism, and has thus been able to follow clues imperceptible to one less well equipped.

What emerges from this careful and original study is that, in spite of its paraphernalia of alembics, cucurbits, pelicans, and furnaces, alchemy was essentially a religious philosophy aimed at the unification of all Nature in a single scheme under Divine guidance: there is a causal chain of descent from God to matter. As the author points out, this is compatible with Christian theology, but it is equally compatible with Muslim theology; allowing for Muslim disbelief in the Trinity and in the divinity of Christ, it is possible to trace quite clearly the continuity of alchemical philosophy from the Brethren of Purity to Thomas Vaughan.

Dr. Sherwood Taylor makes the further point that, owing to its religious basis, alchemy would have no truck with black magic. This is an interesting suggestion, and it is to be hoped that the author will expand it in a further book or paper; the dividing line between alchemists and magicians was surely not always very well defined.

While I have directed attention to what seem to me to be the important contributions to alchemical studies made in the book, it should be added that the main story is a beautifully written and well illustrated account of alchemy from the earliest times: quite the best account yet given in such compass. It will interest all who are curious about man's interpretations of Nature and its relations to the Deity, and, if it be the history of an error, the error was one extremely tenacious of life. It is, indeed, not dead even in this twentieth century. I remember seeing a practising alchemist of the old school, Al-Hajj Abdul-Muhyi Arab (once Mufti of the Shah Jehan Mosque at Woking), absorbedly bending over a heated ladle which was always going to, but never did, deliver a golden stream of transmuted lead.

E. J. HOLMYARD

PHYSICAL CONCEPTS, NEW AND OLD

The Scientific Adventure

Essays in the History and Philosophy of Science. By Prof. Herbert Dingle. Pp. ix+372. (London: Sir Isaac Pitman and Sons, Ltd., 1952.) 30s. net.

THE author of this collection of essays and lectures presides over one of the most interesting and progressive academic 'schools' in Great Britain—that of the history and philosophy of science in the University of London. Thus it is appropriate that he should divide his book into two sections, one historical and one philosophical. As he is at pains to point out, however, he is more specifically in his element when concerned with the latter than with the former. Nevertheless, of the past he has much of consequence to say.

Although composed for a wide variety of occasions, there is a certain thread of continuity running through these pages, a strand of astronomy, astrophysics and cosmology deftly intertwined with their associated epistemological correlates. Amidst much of importance, there should be little difficulty in recognizing that Chapters 1, 9 and 19 (the last) are outstanding in their respective fields. To these, therefore, in general, this review will be restricted. But before getting to grips, one notices how true to type they are. The first, being frankly historical, leaves us to draw—as indeed we must—the conclusions based upon several centuries of scientific endeavour. The other two are quite different in that they propound questions possibly unanswerable. This seems perfectly legitimate, and in full accord with the traditional duty of a philosopher, especially since many an ordinary person (if such exists) would scarcely dream that such problems were stuff for thought at all, let alone disciplined inquiry. It is the merit of these papers that, through reading them, attention is inevitably directed to the presence of several formidable philosophical hurdles confronting the individual and society. There may be little inclination to try to jump them, but to know that they are there is salutary.

Chapter 1 describes what are in effect two life-lines, one that of the logical development of scientific knowledge, the other the actual. Naturally, at certain points they intersect. Broadly, however, the factual course is strewn with minor deviations which lead nowhere, whereas the chart of formal progress is dead straight. Prof. Dingle points the moral clearly. The logical *Lebenslauf* is the lot of the student, if only for the reason that to wander aside into history might touch off some sparks of interest, and thus endanger his effective working hours. As things are, it is only rarely that he has any chance of appreciating how major discoveries and inventions came about; he is constrained largely to pool them in order to get some kind of tidy conspectus. Experience, however, goes far to condemn this tendency, because it is crystal-clear that the capacity for original work of the highest order is more often than not found in those who have deliberately studied the past and pondered over its message.

Turning now to Chapter 9, this deals with "the philosophical viewpoint of the scientist". The emphasis is upon two anomalies, to which the author has devoted a great deal of thought. One is the subject–object relation. The other concerns time. The solution offered is to regard the subject "as inevitably stationed at the present", whereas the object is to recede into the past. Following upon this, reason is seen not to be objective "in the act of thought", whereas experience is found to be placed in time.

Towards the end of this chapter comes the link which seems to join it without constraint to Chapter 19. This is the problem of ethics. We are faced with the Kantian co-equals, 'practical reason' and 'pure reason'; and, sure enough, back we are driven to the categorical imperative. This the author fails to find coercive, and, philosophically speaking, the majority of mankind will agree with him. But, once again, nothing can be done about it.

From here, the reader may well survey the last contribution as from a point of vantage. Its subject is "science and religion". Even to anyone a little wearied of such a theme, it must appear as exceedingly well conceived. Perhaps the reason for this is because Prof. Dingle refuses to get bogged down in the *minutiæ* of what will always, on this side Jordan, be essentially subjective and personal experiences. Yet—and here is the strength of this particular presentation—they are none the less real for that.

Time was, and perhaps to some degree still is, when philosophy was the accredited handmaid of theology, and proud to share a palace with the queen of the sciences. This ancillary relationship has since become somewhat difficult. It is not wholly a question of 'abdication'; events have made it less easy for 'the Crown' to keep clear of, and to sit above, the stresses and strains of contemporary life. But these are matters only discernible maybe upon another plane of discourse, namely, that on which we shall know, even as we are known.

F. I. G. RAWLINS

Quantum Mechanics of Particles and Wave Fields

By Prof. Arthur March. Pp. x+292. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1951.) 44s. net.

PROF. A. MARCH'S book is a very welcome addition to the literature of modern developments in the quantum theory of particles and wave fields. The changes in centres of interest in this subject are well indicated by the fact that one-half of this book is devoted to the subject of relativistic wave equations, and to the quantization of wave fields. The earlier chapters give a good introduction to the earlier developments in quantum theory, including, of course, Schrödinger's wave equation and the principles of matrix mechanics. The later chapters are peculiarly interesting and suggestive, as they deal with the central problems of quantum electrodynamics.

There is a curious passage on p. 179 which seems, at least on the surface, to be at variance with the usual interpretation of Dirac's wave equation. Prof. March writes: "It is important to realize the physical significance of the wave equation (248) [that is, Dirac's wave equation]. It has been emphasized already that this equation no longer permits an interpretation in the sense of non-relativistic quantum mechanics. As long as it is not quantized, it has no relation whatever with particles, but controls the behaviour of a field that is not purely symbolic but actually represents a physical reality. This is clear from the fact that, according to (249), (251), and (253), the field possesses charge, energy, and momentum, and thus it can be measured relative to these observables. It is only a question, then, as to whether wave fields corresponding to the assumed equation really exist, a question that must be answered in the affirmative". This interpretation is so unusual that Prof. March might well have referred to the fact that most writers, including Dirac himself, regard the relativistic wave equation as referring to the behaviour of an individual particle.

G. TEMPLE

The Lipids

Their Chemistry and Biochemistry. By Prof. Harry J. Deuel, Jr. Vol. 1: Chemistry. Pp. xxiv+982. (New York and London: Interscience Publishers, Inc., 1951.) 18.50 dollars.

THE term lipid has been interpreted in its fullest sense, and the author discusses not only the simple lipids (fats and waxes, 405 pages) but also the compound lipids (phosphatides and cerebrosides, 102 pages) and the derived lipids (carotenoids, 160 pages, and vitamins A, D, E and K, 194 pages). The author does not claim to be an authority in all these fields, though it is suggested, in the preface, that this will make the book less involved and therefore more understandable to non-specialist readers.

For so large a book, the number of mistakes is small, though some have been noted. For example, the formulæ on p. 168 (1 : 2-benzylidene glycerol), 428 (choline chloride) and 602 (azafrinone) are in error. It is stated (p. 88) that linolenic and elæostearic acids are the only octadecatrienoic acids known; but octadec-6 : 9 : 12-trienoic acid, reported to occur in *Œnothera biennis* seed oil, is a member of this series. The statement (p. 242) concerning the low iodine value of linolenic acid seems doubtful, while the section on atmospheric oxidation of unsaturated fatty acids and their natural derivatives is somewhat inadequate, making no reference to the important new developments reported in this field by many workers during the past decade.

Despite these errors and omissions, the general style of the book is pleasing, and I have read it with profit and enjoyment. References are copious, and the indexes (121 pages) appear to be very complete. The book is most useful to the reader in those parts of the field in which he is not a specialist.

F. D. GUNSTONE

A Basic Course in the Theory and Practice of Quantitative Chemical Analysis

By Prof. George L. Clark, Prof. Leonard K. Nash and Prof. Robert B. Fischer. Pp. xxi+448. (Philadelphia and London: W. B. Saunders Co., 1949.) 21s.

QUANTITATIVE analysis is one of the fundamental branches of the science of chemistry, and the proper instruction of the beginner in the broad essential aspects of the subject is invaluable to him in whichever field he may eventually specialize. This book, written by three authors with considerable experience in the teaching of analytical chemistry, forms an excellent introductory course for students.

Part 1 deals with gravimetric analysis, and Part 2 with volumetric analysis, the method of presentation in each case being a logical combination of theory and practice. Three representative determinations have been treated with unusual care and completeness in order to lead the inexperienced student to the proper critical approach to the subject, the later methods being dealt with in somewhat less detail. Part 3 describes briefly the modern instrumental methods of analysis. Many of the chapters are followed by review questions and problems which serve to test the reader's grasp of the subject-matter. Part 4 consists of ten short appendixes, including those on essential mathematics for quantitative analysis, standardization of weights and statistical treatment of experimental data.

The book is well written and well produced, but, from the British reader's point of view, the use of such terms as "precipitimetry" and "complexometry" is to be deplored.

A Text-Book of Practical Organic Chemistry, Including Qualitative Organic Analysis

By Dr. Arthur I. Vogel. Second edition. Pp. xxiii+1033. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1951.) 50s. net.

THE issue of a second edition of this laboratory manual only three years after the publication of the first edition (see *Nature*, 161, 995; 1948) is evidence of the popularity which it has deservedly achieved. The new edition is, in fact, little more than a reprint. For the most part the pagination corresponds with that of the first edition; but it is stated that the opportunity has been taken to correct various minor errors and to incorporate some suggestions made to the author. The appendix is enlarged by the inclusion of examples of new preparative methods in common use. These are the formation of some acetylenic compounds by liquid ammonia reactions; the use of N-bromosuccinimide, the Huang–Minlon modification of the Wolff Kishner reaction; reductions with lithium aluminium hydride; cyanoethylation; and the use of organo lithium compounds. These are welcome additions. There is no doubt that this book has established itself as a medium of instruction in practical organic chemistry.

J. W. COOK

METEORITES AND COSMIC RAYS

By Dr. S. F. SINGER

Office of Naval Research, U.S. Embassy, London

THE extensive measurements of Paneth and his collaborators[1] of the uranium, thorium and helium content of iron meteorites have established a method for determining the time elapsed since their solidification. The widely varying 'ages' obtained by this method have led Bauer[2] and also Huntley[3] to suggest that cosmic rays may provide an additional source of helium and therefore affect these determinations. Certain of Bauer's more detailed conclusions have been criticized[4]; but it seems very likely that the ages quoted[1] represent upper limits. (Underlying all of this work is the assumption, for which there is experimental support[5], that the diffusion of helium, and therefore its loss, is negligible at ordinary temperatures due to the structure of iron meteorites.)

The problem of helium production by cosmic rays has therefore been re-examined[6]. (1) By taking into account the important contributions of cosmic-ray secondaries and other factors, one obtains a lower limit for the rate of helium production which is more than an order of magnitude greater than Bauer's value. One also comes to a conclusion different from Bauer's about its variation with depth in the meteorite. These calculations can be checked by related experiments; a calibration may also be obtained from self-consistent age measurements on a single meteorite. (2) A method is developed here for separating experimentally the helium contribution by cosmic rays and by radioactivity; it is based on the fact that cosmic rays are able to produce substantial amounts of helium-3 either directly or through tritium, whereas the radiogenic helium consists entirely of helium-4.

The results of such studies on the total amount of radiogenic and cosmic-ray helium can then be applied to give a correction to the age determinations of meteorites and to other cosmological problems[6].

Production of Helium

A number of processes are known by which the cosmic radiation can produce helium in meteorites (strictly speaking, 'meteoroids'). The most important contribution comes from the excitation of iron nuclei by fast cosmic-ray particles, and the subsequent evaporation of helium-4 and helium-3 nuclei, and of tritium nuclei which decay into stable helium-3. Other processes of lesser importance contribute to the helium production, namely: (1) primary helium nuclei stopping in the meteorite; (2) helium fragments from the break-up of heavy primary nuclei; and (3) heavy unstable nuclei ejected in cosmic-ray induced disintegrations ('stars') which break up into α-particles[7].

These events differ in some respects from those occurring in the atmosphere. The effect of the higher atomic weight of the meteorite will be to change the characteristics of the 'average' star[8], while due to the much higher density of the meteorite most π-mesons (themselves produced in nuclear encounters) will interact before decaying into non-interacting μ-mesons, and thus carry the helium production process to greater depths. (On the other hand, the effects of low-energy neutrons which produce tritium in the atmosphere[9] can be neglected here.)

The rate of production of helium-3 and helium-4 in iron has been calculated in two essentially different ways; they lead to concordant results. One method uses a cosmic-ray flux figure extrapolated from measurements on the primary radiation, empirical interaction cross-sections, and results of evaporation theory[10]. The other more empirical approach combines certain features of evaporation theory with a statistical study based on about 12,000 cosmic-ray stars, obtained by the University of Bristol group in high-altitude exposures.

Not only the primary radiation, but also lower-energy secondaries (protons, neutrons and π-mesons) are effective in producing stars. For this reason the amount of helium produced reaches a rather flat maximum some distance from the surface of the meteorite, and falls off rapidly with distance only after a depth of about 25 cm. The results given here apply for the case of an infinitely large meteorite having a nearly plane boundary. (In practice, this would correspond to a 'pre-atmospheric' diameter rather greater than one metre.) For meteorites of small size or odd shape, these results can be used, together with a suitable numerical calculation to take proper account of the solid-angle factor.

The final numerical value for the rate of helium production (by a flux of cosmic rays corresponding to the present-day value in the vicinity of the earth's orbit) in the region 2–15 cm. from the surface of an iron meteorite is $(5 \pm 1\cdot5) \times 10^{-14}$ c.c. of helium at N.T.P. per gm. of meteorite material per year. Of this amount ~ 30 per cent is calculated to end up in the form of helium-3.

The errors given are estimated ones and based on the present state of knowledge of cosmic-ray processes. In any event, it is thought unlikely for the rate of production to be appreciably lower, since all known cosmic-ray effects are believed to be taken into account. It should be pointed out also that the fraction of helium in the form of helium-3 decreases slowly with decreasing mean energy of the star, and hence with increasing depth in the meteorite.

These estimated errors are not likely to be reduced appreciably by further refinement of the calculations. A more promising approach, particularly with regard to the ratio of helium-3 to helium-4, comes from the experimental side, where one can attempt to simulate in the laboratory the exposure of meteorites to cosmic rays. As a first step in this direction, Dr. W. Barkas has kindly exposed a stainless steel target in the Berkeley 340-MeV. proton synchrocyclotron; this sample is now being analysed at the University of Durham. It is hoped to continue this approach by exposing a suitable sample in a bevatron, which produces protons in the cosmic-ray energy region. Independently, an experimental check on certain features of the evaporation theory and its application to an iron nucleus can be obtained by analysing by means of a magnetic field and nuclear emulsions the evaporation products of stars produced by cyclotron protons[11]. Following a different line of attack, nuclear G-2 and G-5 emulsions loaded with thin iron filaments have been obtained through the courtesy of Prof. G. P. S. Occhialini (Brussels) and Mr. C. Waller (Ilford, Ltd.). These have been exposed to the cosmic radiation at mountain altitudes.

Age Correction

Making the proper correction to the meteorite age requires the subtraction of cosmic-ray helium from the helium sample extracted from the meteorite. (A typical sample would amount to $\sim 10^{-6}$ c.c. helium per gm. of meteorite.) It is necessary first to measure the amount of helium-3 in the sample. After subtracting the helium-3 plus the proper amount of cosmic-ray helium-4 (calculated from the ratio above), one is left presumably only with radiogenic helium-4. The age can then be calculated by conventional methods[1].

The helium isotope ratio in the sample can probably be determined with modern mass-spectrometric equipment[12]. For very small samples, however, a radiochemical procedure based on Coon's method[13] may also be of value. Helium-3 is known to have an extremely large absorption cross-section (about 5,000 barns) for thermal neutrons. The (*n,p*) reaction occurring produces tritium, which is β-unstable and is transformed back into helium-3 with a half-life of 12 years. Exposure of a helium sample containing only 10^{-6} c.c. of helium-3 in a nuclear pile for a few days would give sufficient tritium to produce a measurable activity. It is proposed to determine the helium-3 content of the meteorite sample by comparing this activity with those from calibrated samples (enriched with helium-3) exposed under identical conditions. (Even smaller amounts of helium-3 could be detected by the use of special triton counters[14].)

In view of the fact that a unique age should result from a series of corrected age determinations obtained from different parts of the same meteorite, it may be possible to obtain a consistency check of the numerical result given in this article for the cosmic-ray helium isotope ratio and a calibration of the variation of this isotope ratio with depth in the meteorite.

Meteorites as Integrating Cosmic-Ray Meters

Some additional applications of the cosmic-ray helium method to problems of cosmological interest are pointed out here. These remarks must be viewed with some reserve, because of the many uncertainties about the physical history of meteorites. (For example, the helium gas may have diffused through the meteorite and have escaped if the latter was exposed to high temperatures.) Essentially one wants to provide an experimental test for the following assumptions: (1) the meteorite has been exposed directly to the primary cosmic rays from the time of solidification to the time of chemical analysis (that is, over the whole time interval during which radiogenic helium was allowed to accumulate); (2) this primary cosmic-ray intensity experienced by the meteorite corresponds to the flux in the vicinity of the earth; and (3) the average intensity over the life-time of the meteorite corresponds to the present-day intensity.

(1) By making use of the fact that cosmic rays produce helium in meteorites, one can develop the concept of considering a meteorite as an integrating cosmic-ray meter which gives one the time and space integral of the cosmic-ray flux it encounters over its path and life-time. From the corrected age of the meteorite and the amount of cosmic-ray helium, an empirical rate of helium production by cosmic rays can be determined and compared with the rate calculated on the basis of the assumptions just stated. It may then be possible to gain information about the cosmic-ray intensity in prehistoric times; or the intensity in the region where the meteorite spent the major part of its existence. A low value of cosmic-ray intensity obtained in this way may also be interpreted by assuming that the meteorite did not become exposed to cosmic rays until some time after its solidification, or that it landed on the earth during prehistoric times.

(2) By virtue of the fact that (in very large meteorites) the production of helium by cosmic rays is a 'surface effect' as opposed to the volume effect of radioactivity, one may hope to learn more about the physical processes undergone by the meteorite in its creation and in its travel through space. In particular, by determining its loss of mass in its traversal of the earth's atmosphere, it may be possible to establish an experimental test for the theory[15] of astroballistic heat transfer of a meteorite.

Full details of the present work will appear in *Geochimica et Cosmochimica Acta*. Experimental work on the possibility that helium-3 exists in meteorites is now in progress.

I want to express my thanks to Prof. F. A. Paneth for his interest in this work and for many stimulating discussions, also to U. Camerini, D. H. Perkins and S. Sørensen for valuable comments.

Dr. S. F. Singer has kindly shown me the preceding paper. It may interest readers that in a recent article[1] containing various experimental results—obtained partly in collaboration with the Clarendon Laboratory in Oxford—figures are given for the helium-3 content of five iron meteorites. They are in very good agreement with Dr. Singer's theoretical deductions, as can be seen from the accompanying table.

Name of meteorite	Helium content in 10^{-6} c.c./gm.	Helium-3/helium-4 (%)
Mount Ayliff	36·8	31·5
Carbo	22·0	28·0
Toluca (Durham)	18·9	29·7
Bethany Amalia (Krantz)	3·4	27·8
Bethany (Harvard)	0·36	17·8

For a discussion of these results in connexion with the question of the age of meteorites, the article referred to above in *Geochimica et Cosmochimica Acta* should be consulted.

ADVANCES IN THERMODYNAMICS

THE first of the laws of thermodynamics discovered was the second, by Carnot in 1824, when he described the cycle known after him and stated 'Carnot's theorem' that the work done in any reversible cycle operating between two temperatures is proportional to the heat supplied at the higher temperature and to the difference of temperatures. This was put into symbolic form by another engineer, Clapeyron, in 1834. Let a quantity of heat q fall through a temperature difference $\delta\theta$ in a reversible cycle and let the work w be done in the cycle, then:

$$w = Cq\,\delta\theta,$$

where C is a function of the higher temperature θ only. The work is $\Delta V \mathrm{d}p$, where ΔV is the volume change at the higher temperature and $\mathrm{d}p$ is the difference of pressures at the higher and lower temperatures; hence:

$$\mathrm{d}p/\mathrm{d}\theta = Cq/\Delta V. \tag{1}$$

Both Carnot and Clapeyron adopted the prevailing 'caloric' theory of heat, according to which heat is a material fluid (q equals a constant), and explained the production of work by the 'fall' of caloric through a temperature difference, just as work is obtained from a weight falling between two levels in a gravitational field. 'Energetics' later postulated that every form of energy is a product of two factors, quantity (for example, caloric for Carnot) and intensity (for example, temperature).

The first law of thermodynamics followed about 1849 with the work of Joule, and required that the heat absorbed in the cycle is not indestructible (as Carnot himself had suspected) but part appears as work. William Thomson (later Lord Kelvin) had shown that the original Clapeyron equation (1) gives correctly the effect of pressure on the melting point of ice, and that it could give an 'absolute' definition of temperature. We could say now that if heat, like work, is a form of energy, $\mathrm{d}p\Delta V$ and q have the same dimensions, and hence C in (1) must be the reciprocal of a linear function of temperature, $a + b\theta$; and by assigning suitable values to a and b, an absolute temperature scale, including the zero and the size of the degree, can be obtained. This was done by Thomson in 1850, after he had shown that Clapeyron's equation is still true when some heat disappears. In fact, in (1) only the heat taken in is concerned. In 1850 Thomson and Clausius, independently, stated the second law in its modern form; but Thomson did more. In 1855 he noticed that (1) can be written in the form:

$$\mathrm{d}w = q.\mathrm{d}T/T, \text{ or } (\mathrm{d}w/\mathrm{d}T) = q/T, \tag{2}$$

and since:

$$q = \Delta E + w, \tag{3}$$

where ΔE is the energy increase of the system in the finite change at the higher temperature in the cycle and w is the work done:

$$\mathrm{d}w/\mathrm{d}T = (\Delta E + w)/T. \tag{4}$$

In these equations, T is the absolute temperature reckoned from zero, in the way suggested by Thomson. Equation 4, which combines both laws of thermodynamics, has received various names, a favourite being the 'Gibbs–Helmholtz equation'. It was never stated or used by Gibbs, and was published by Helmholtz only in 1882. Nernst used it in the form:

$$A - U = T(\mathrm{d}A/\mathrm{d}T), \tag{5}$$

where $A = w$, $-U = \Delta E$.

In 1879, Thomson introduced the name 'motivity' for the part of the energy of a system available for conversion into work. The motivity at constant temperature was renamed 'free energy' by Helmholtz in 1882, and he gave it the symbol F. Hence:

$$w_T = -\Delta F, \tag{6}$$

and from (4):

$$\mathrm{d}\Delta F/\mathrm{d}T = (\Delta F - \Delta E)/T. \tag{7}$$

Thomson showed that his equation 4 applies to various kinds of work, and that it embodies a general law. He also stated that in all actual (irreversible) processes there is a diminution of free energy, which he called a "dissipation of energy".

In 1876, Massieu used the free energy F and another function of state:

$$G = F + pV, \tag{8}$$

such that in isothermal changes at constant pressure, $-\Delta G = -\Delta F - p\Delta V$ is the work done minus the external work (not, as beginners are apt to think, the work done at constant pressure). These functions were much used by Gibbs in 1876, who wrote $F = \psi$, $G = \zeta$, without giving names to either. It is shown above that the name 'Helmholtz free energy' for F is a misnomer.

A useful subsidiary function, the chemical potential μ, first used by Maxwell in 1874 but extensively applied by Gibbs, may be defined as:

$$\mu = \mathrm{d}F/\mathrm{d}m, \tag{9}$$

where $\mathrm{d}m$ is a quantity of a component introduced under specified conditions. This makes the energy equation for a multi-component system take the form:

$$\mathrm{d}E = \Sigma X \mathrm{d}x, \tag{9a}$$

and by Lagrangian transformations many useful subsidiary equations, including those in $\mathrm{d}G$, are at once obtainable. In the absence of radiant energy such a form may usually be specified.

With the work of Thomson and Clausius outlined above, classical thermodynamics may be said to have reached maturity. Thomson in 1898 showed, in fact, that all the fundamental equations may be stated in terms of E and F, defined as above. In 1864, however, Clausius introduced another derived function S, which he called the entropy. This is quite useful and is given by (2) as:

$$S = \mathrm{d}w/\mathrm{d}T = -\mathrm{d}F/\mathrm{d}T, \tag{10}$$

and hence from (4) by:

$$\mathrm{d}S = \delta q/T \tag{10a}$$

in reversible processes. It is seen that F and G are expressible in the forms:

$$F = E - TS;\ G = E - TS + pV. \tag{11}$$

Since F decreases in irreversible changes, S increases; in equilibrium F is a minimum at constant volume and temperature and S is a maximum at constant energy. S cannot claim to be more fundamental than F, and was introduced rather late, when most of the derived equations of thermodynamics were familiar.

The first applications of thermodynamics to chemistry go back to Horstmann, who, from 1869, used it in studies of dissociation. The most important pioneering work in this field, however, is that of van't Hoff in 1885. He not only carried over the equations for ideal gaseous systems to ideal solutions, but also gave equations for the work done in reversible chemical changes in such systems, and the change of equilibrium constant with temperature. Van't Hoff made use of cyclic processes, in which selectively permeable membranes are employed to separate the constituents of mixtures. All subsequent developments of chemical thermodynamics show the influence of van't Hoff's work.

Thomsen in 1854 and Berthelot in 1864 had suggested that, in chemical changes :

$$w = - \Delta E ;$$

and although this is seen to lack general validity from the point of view of equation 4, it is found experimentally to be approximately true in so many cases that some relation between ΔE and w, or alternatively between E and F, not contained in the two laws of classical thermodynamics, may be suspected. Such an approach, on the basis of experiment, is apt in many cases to disclose new laws, and is abundantly more fruitful than arguments based on symbolic equations. It was Nernst in 1906 who disclosed this new relation, called after him the 'Nernst heat theorem'; since it has limitations, the name 'third law of thermodynamics' sometimes used for it is unsuitable. The theorem states that in reactions between pure solids :

$$\mathrm{d}w/\mathrm{d}T = 0 \text{ when } T \rightarrow 0, \qquad (12)$$

when (4) shows that $\Delta E = - q_v$ is equal to w. Equations 3 and 10*a* then show that :

$$\Delta S = 0 \text{ when } T \rightarrow 0. \qquad (13)$$

A special case, in which S for every reacting solid is zero when $T \rightarrow 0$:

$$S = 0 \text{ when } T \rightarrow 0, \qquad (13a)$$

was proposed by Planck in 1911. Even if this is not true, we have no means of finding the absolute entropies at $T = 0$, and (13) shows that they are irrelevant in calculations; hence Planck's form is now always used. It at once enables S for any material to be calculated for any state (solid, liquid, or gaseous) from specific heats only, by integration from $T = 0$, when all specific heats are seen from (13*a*) to be zero. From S and known values of ΔE, the values of ΔF may be calculated. When these are known, the equilibrium constants of chemical reactions may be found by an equation deduced by van't Hoff in 1885, which, with suitable standard states, may be written in the form :

$$- \Delta G = RT \ln K \qquad (14)$$

for ideal gases or ideal solutions, where $\ln K$ is the natural logarithm of the equilibrium constant. A whole field of chemical thermodynamics is thus opened out.

A useful subsidiary function introduced by G. N. Lewis in 1907 enables (14) to be carried over to non-ideal systems. Instead of using the concentrations in K, it is possible to introduce quantities called activities which are functions of concentration, $a = fc$, where f is an activity coefficient. Lewis derived his equation by cyclic processes, which have always proved attractive to discoverers of new principles in thermodynamics, but the most convenient form is :

$$\mathrm{d}\mu = RT \ln a, \qquad (15)$$

where μ is the chemical potential. From (15) the equations of Lewis's scheme may be derived.

In the latest, modern, phase of thermodynamics, Thomson was also a pioneer. Both he and Maxwell clearly realized about 1870 that, when the atomic constitution of matter is brought into the picture, the second law of thermodynamics loses its general validity, since processes involving individual molecules which violate it, without disagreeing with the first law, can be imagined. The second law is true for systems composed of very large numbers of molecules, which behave like large populations and for which predictions based on statistical principles or probabilities can be used. Thus it is true only in a statistical sense. The development of this idea by Boltzmann and Planck led to a new science, statistical mechanics, which supplements the classical second law and limits the range of validity of the Nernst heat theorem. In this region, alternative types of statistics apply. Maxwell–Boltzmann statistics, based on classical mechanics, applies with close approximation in most cases, though probably never exactly, while in systems subject to laws governing quantum, as contrasted with continuous, energy changes, new types of statistics are used. One of these, due to Bose and Einstein, gives Planck's radiation formula. At present, the close relation of thermodynamics to statistical mechanics makes it desirable to deal with both in a text-book on thermodynamics, although statistical mechanics has many applications outside that subject.

All the equations of thermodynamics apply only to reversible processes. All real processes are more or less irreversible, and will be represented by inequalities, conformable with the condition that the free energy will be decreasing, or the entropy increasing, more than for a reversible change. A locomotive drawing a train at high speed with the regulator valve fully open is wasting much energy in friction, which is greater the higher the speed. In running up a gradient, the speed drops and, since there is less friction, the efficiency increases. The maximum efficiency is reached when the gradient is so stiff that the train is on the point of stopping, and all reversible processes, which are successions of equilibrium states, take place infinitely slowly, since they never really take place at all. Time has no place in classical thermodynamics.

Some reversible changes are, by their nature, always accompanied by irreversible ones. In his treatment of thermoelectricity, Thomson assumed that the reversible Peltier and Thomson effects could be treated independently of the irreversible Joule effect of heat production due to resistance, and similar assumptions have been made elsewhere. Since the results agree with experiment, they must be justified. It is only quite recently, however, that an attempt has been made to systematize such procedures in the case of steady states, when as much heat is entering an element of the system as is leaving it in the same time. The irreversible generation of entropy in the system due to the flow of heat is then known. One approach seeks to combine equations 9*a* and 10*a*, X being a generalized force and x being replaced by a rate of flow in steady states. A linear relation is assumed (which will not be true in some cases) and the general form is a tensor, which may be symmetric. If it is assumed that a temperature exists in every volume element, an equation giving the rate of generation of entropy as the sum of the products of the generalized forces and generalized flow-rates, divided by the temperature, is obtained. The subject is important, and a promising start has been made, which has proved useful in several fields. This is the newest phase of thermodynamics.

The books referred to below* deal with the applications of thermodynamics in chemistry; but that by Denbigh is of wider interest. They are all good and useful and can all be warmly recommended. Allard's book is very clear and interesting, starting at the beginning and deducing the equations from the fundamental laws. It has a fairly long section on the phase rule, which seems out of place, a good section on statistical mechanics, and a clear account of such parts of wave mechanics as are needed in this. The treatment is modern and the mathematics has been presented in an understandable form. It is a book very suitable for students.

The books by Rossini and Paul are based on the Lewis system; fugacity is rather fully dealt with by Rossini but only in passing by Paul. Both books attempt to start at the beginning. Rossini makes heavy weather of free energy by approaching it from entropy, and has more than a page in finding what is equivalent to equation 6 above, at the same time making it clear that ΔG is only part of the free energy change, a point not always evident in American books. Rossini's definitions are careful and clear, but it is not obvious why he should bring in atomic energy in such detail, since thermodynamics does not deal with nuclear changes. In both books the symbol F is used for G, and it is called free energy, which is confusing. Rossini, as might be expected, lays particular emphasis on experimental data, and his accounts of the calculation and use of thermodynamic quantities are admirable. He has not much to say of irreversible processes. Paul gives the usual treatment based on Clausius, which is not very clear; he could with advantage have reconsidered this topic, since he obviously has the capacity for understanding difficult subjects and making them clear to students. Both Rossini and Paul deal with the Debye–Hückel theory of strong electrolytes, but only Rossini deduces the equations. Both books deal with statistical mechanics, Paul's account being more readable and likely to be more intelligible to beginners. Both have problems, and Paul's gives answers. A section at the end of Rossini's book deals with the applications to such technical problems as fractionation, which should be useful to young chemists entering industry and called upon to put their knowledge into practice. In short, the books by Paul and Rossini are sound treatises written on American lines and bringing Lewis and Randall up to date.

Denbigh's book, I think, is not quite successful. It deals in a limited space with a rather difficult subject. It makes several re-starts on the same topic, which leaves the impression of a certain breathlessness, the i and k subscripts on pp. 27–29 are confusingly jumbled, and some of the statements, such as the one on p. 61 that both energy and entropy in thermodynamics are simply mathematical quantities, are rather startling. The real meaning of the heat of transport is not made very clear at the start, and the introduction of time into thermodynamics is not justified; the procedure of converting an equation into a kinetic equation by dividing by dt (p. 46) requires more justification, and the statement that de Donder's treatment of thermodynamics is better than Lewis and Randall's (p. 45) would not be approved by Allard, who shows in his book (p. 198) that it has some undesirable features; and is also clear (p. 72) that the application of the principle of increase of entropy to a 'universe' is meaningless unless the universe is defined as a thermodynamic system, which is not done by those using the idea.

The subject of thermodynamics has developed very much in recent years, and much of this has come about by reason of its applications in chemistry. The chemist needs to know what is contained in such books as the above, and it would do the physicist and engineer no harm to know it either. The method of treatment suitable in the study of heat engines is less applicable in chemistry, and the special methods used in that science have amplified the scope of the subject and have also provided a bridge between classical thermodynamics and statistical mechanics which has led to many valuable interchanges of material from the two sciences. The study of irreversible changes still remains undeveloped and difficult; but the material summarized in Denbigh's book shows that progress is being made in this field, and we may hope that before long many new fields of application will have been developed. Let those who think that thermodynamics is a closed subject reflect.

MOISTURE RELATIONS AND FIBRE PROCESSING

DURING the morning of September 9 at the recent meeting in Belfast of the British Association, Section A (Physics) held a session on the moisture relations of textile fibres, which consisted of two papers, one by Mr. J. A. Matthew, head of the Spinning Department of the Linen Industry Research Association, entitled "Moisture Absorption by Fibres and its Effect on Fibre Properties", and the other by Dr. A. B. D. Cassie, director of research at the Wool Industries Research Association, entitled "Moisture Relations and Clothing Comfort".

Mr. Matthew dealt with three main aspects of the problem. He discussed the relation between the amount of water absorbed by textile fibres and the atmospheric temperature and relative humidity, and also the effect of the absorbed water upon the physical properties of the fibre. He then gave some practical examples of the effect of humidity on the efficiency of the processing of flax fibres and yarn during spinning and weaving.

If fibre, yarn or cloth is stored in an atmosphere maintained at a constant temperature and relative humidity, the moisture content of the material, expressed as a percentage of the oven-dry weight, gradually attains a steady value called the 'equilibrium regain'. The equilibrium regain of all textile fibres and their products depends primarily on the relative humidity and temperature of the air, but other factors, including the previous history of the material, also have their effect. If the material is wetted out and then allowed to reach its equilibrium regain at a constant temperature and at a series of progressively decreasing relative humidities, the regain values lie on a sigmoid desorption curve when plotted against the relative humidity. When the process is continued with ascending humidities, the regain values lie on a second sigmoid absorption curve which lies below the desorption isotherm curve, except at very low and very high humidities. A similar hysteresis effect occurs when absorption takes place as a result of increasing the humidity after partial desorption or when desorption occurs after partial absorption. Hysteresis also occurs when the material is brought to equilibrium in an atmosphere of constant humidity at temperatures which are progressively increased and afterwards decreased.

These effects are shown by the following materials : cotton, flax, hemp, jute, etc. ; wood, silk and hairs ; fibres manufactured by the regeneration of cellulose ; and some other materials such as wool and starch. For all these materials the absorption and desorption isotherms are very similar in shape, so that the ratio of the equilibrium regain of one material to that of another is very nearly the same at all humidities.

A few manufactured fibres such as cellulose acetate, nylon and 'Terylene' do not behave in this way. There is no point of inflexion in the curve at low humidities, the regain is quite small at all normal humidities, and there is very little difference between the absorption and desorption isotherms.

The equilibrium regain at given atmospheric conditions differs from one type of fibre to another. For example, at 65 per cent relative humidity and 65° F. (18·3° C.) average values are as follows : wool 14 per cent, viscose rayon 13 per cent, green flax 11 per cent, silk 9·5 per cent, raw cotton 8 per cent ; but with all natural fibres the equilibrium regains of different lots differ according to their origin and treatment.

The physical and mechanical properties of textile fibres depend upon the humidity of the air to which they have been exposed, and Mr. Matthew went on to deal with these effects in detail. The strength of fibres and of the yarns and cloth manufactured from them depends upon the humidity of the atmosphere in which they have been conditioned. Vegetable fibres usually increase in strength with increase in relative humidity, whereas the reverse is the case with artificial and protein fibres ; for example, linen yarns increase 25 per cent in strength when the humidity is increased from 50 to 90 per cent, whereas viscose rayon loses 40 per cent of its strength under similar conditions. The moduli of elasticity and rigidity of fibres decrease with increasing relative humidity. The frictional properties of textile fibres and yarns increase rapidly with increase in humidity ; but in most cases there is a reduction in the friction when a free film of water is present. The electrical properties of fibres and their products vary considerably with the regain. The conductivity of fibres is extremely low at low regains but increases very rapidly with increasing regain, while the dielectric constant remains fairly constant at low regains but thereafter increases rapidly with increase in regain. The variation in the electrical properties with regain forms the basis of electrical moisture meters ; and, although the accuracy of these instruments is limited by differences between the behaviour of different batches of the material and a separate calibration is required for each type of fibre, the rapidity with which these instruments can be used more than offsets these disadvantages.

The absorption of water vapour by flax and other textile fibres and the consequent effects on their physical properties affect textile technology in many ways. After pointing out the need for control of the relative humidity in checking the weight per unit length of the yarn or the weight per unit area of the cloth, and the strength of the product, Mr. Matthew gave some examples taken from the spinning and weaving of linen, in which the atmospheric humidity has an important effect upon the efficiency of processing. In preparing flax fibre for spinning, the material passes through a number of frames on which it is drawn out by pairs of rollers rotating at different speeds. Fibre is liable to collect or 'lick-up' on these rollers, and when this happens the machine must be stopped for cleaning and so production is lost. 'Lick-up' can be considerably reduced by maintaining the flax at a suitable regain. In dry spinning, productivity is limited by breakages of the yarn, and the rate at which these breakages occur is much reduced by increasing the relative humidity. Similarly, in weaving, stoppages due to breakages of the warp yarn are reduced when the operation is carried out at a high temperature and humidity. Such atmospheric conditions, however, cause fatigue and discomfort to the workers, with a consequent reduction of output, so that in practice a compromise must be sought between the conditions which are most suitable for processing and those which are comfortable for the workers.

Dr. Cassie dealt with the thermal properties of clothing and showed how the interaction of the fibres with the water vapour in the atmosphere contributes in no small degree to the comfort of clothing by liberating heat when the wearer passes from a warm dry atmosphere to a cold damp one. Considering the thermal insulation, Dr. Cassie said that still air is the best insulator known to man, and fabrics make use of this property. The thermal conductivity of fabrics increases with their bulk density, and any increase in the amount of solid material of a fabric leads to a loss of heat insulation. Worsted fabrics contain about 60 per cent air, and the very large total surface area of the fibres—about 2,000 sq. ft./lb. of wool—exerts a very effective drag on the air, which is thus maintained at rest within the fabric and provides excellent heat insulation.

The large surface of the fibres brings them into close contact with the surrounding atmosphere and enables them to interact with the water vapour. Recent research has shown that in such conditions the time required for water to diffuse from the surface to the centre of a fibre is always negligible compared with the time required for the diffusion of water vapour and the transfer of heat through the air entrapped by the fibres. Fibres can react rapidly with heat and water vapour provided that they are presented to the fibre as quickly as required. On the other hand, at normal atmospheric conditions such as 65° F. and 60 per cent relative humidity, each c.c. of wool contains eighteen thousand times as much water as does the same volume of air, and this enormous difference between the water content of wool and air makes the approach to equilibrium slow when there is a relatively large bulk of wool.

The absorption of water vapour by fibres is accompanied by a large evolution of heat, and Dr. Cassie gave as an example the amount of heat liberated by a man's clothes when he goes out of doors from a well-ventilated and -heated room on a typical winter day in Britain. Assuming that the clothes contain five pounds of wool and that they are in equilibrium with the conditions indoors (namely, 65° F. and

45 per cent relative humidity), they will absorb one pound of water when taken outside and allowed to re-condition at 40° F. (4·4° C.) and 95 per cent relative humidity. In so doing they will liberate 1,200 B.Th.U. of heat. This amount of heat will provide excellent protection against the chill of a sudden temperature change provided that it is liberated at a suitable rate, and Dr. Cassie proceeded to show that the conditions within a fabric are such as to ensure that this heat is liberated at the optimum rate for protection against a sudden change of temperature.

The fibres are always in equilibrium with the air immediately surrounding them because absorption and desorption of water take place very rapidly; but the amount of water vapour absorbed from the air is so small compared with the water content of the fibres that their regain is virtually unchanged. The temperature of the air issuing from a mass of wool is therefore determined by the condition imposed by the fibres, namely, that the relative humidity must remain unchanged. The heat obtained by condensing enough water vapour from any given volume of air to maintain a constant relative humidity when its temperature is decreased by 1 deg. C. is roughly equal to the heat required to raise the temperature of the air in the given volume by 1 deg. C. Thus, if the temperature of the air coming into contact with the textile is reduced by 10 deg. C. without change in the water vapour pressure, the air after passing through the textile will only be reduced by 5 deg. C., enough water having been condensed from the air by the textile to raise its temperature by 5 deg. C. This thermostatic effect of textiles is maintained over considerable periods because, fortunately, the diffusion constants for heat and for water vapour are almost the same, being 0·21 cm.^{2}/sec. and 0·25 cm.^{2}/sec., respectively. Thus the temperature and water vapour gradients are correctly maintained for securing the maximum effect in reducing the chill produced by a decrease in temperature.

The results of experiments designed to test the accuracy of these theoretical conclusions were then described by Dr. Cassie, who showed that excellent quantitative agreement has been obtained between the theoretical and actual results. The effect was studied of increasing the temperature of the air, passing through a mass of fibre, from 20° to 35° C. without change of vapour pressure, and it was found that the change in temperature of the emerging air was halted at 26° C. The subsequent rate of increase in temperature was small, being least of all for wool and increasing in the order, wool, flax, silk and cotton. This corresponds to the order of the regains of the fibre, and, as predicted by the theory, the protection afforded by the fibres increases with the slope of the regain – relative humidity curves.

Finally, Dr. Cassie pointed out that a similar large thermostatic effect can result from textile furnishings. The increase in regain of a carpet when a room is left unheated results in the liberation of as much heat as would be given off by a 1-kW. electric fire burning for 1½–2½ hr., the heat being liberated over a period of several days.

In the discussion which followed these two papers, Dr. R. W. Powell described experiments made at H.M. Norfolk Flax Establishment on the moisture relations of the growing flax plant, and pointed out that the normal date of pulling flax corresponds to the time at which the whole plant has a uniform moisture content. He mentioned experiments made on the heating up of stacks of flax straw and also described how the humidification of dry flax straw before scutching increases the yield of flax fibre.

Miss M. V. Griffiths asked whether the airing of domestic linen is really necessary, as a large amount of electricity is being consumed in modern houses for this purpose. Should the air movement be increased during drying in an airing cupboard or could a more efficient drying cupboard be designed? In reply, Mr. Matthew said that he regarded airing as a safety measure; linens stored in a folded condition in drawers would have little access to free air and so would not dry if they were put away damp. The rate of drying increases with increasing air velocity and temperature; usually the most economical method is to use some heat and a definite but not necessarily very large air velocity, on well exposed material. Dr. Cassie said that it is necessary for underwear to be dried to a low regain; measurements have shown that, in the absence of perspiration, the air between the skin and underclothing has a relative humidity of only about 20 per cent, and underclothing should therefore be conditioned to this relative humidity by airing. J. L. SPENCER-SMITH

AFFORESTATION OF MOORLAND

At the meeting of the British Association in Belfast, Section K* (Forestry) devoted a session during the morning of September 8 to the consideration of sylvicultural problems resulting from recent large-scale planting on moorland soils. The need for a considerable extension of the forest area in Britain —a need admitted by men of all shades of opinion— has led to the formation of large plantations on heathland and moorland mainly in the upland regions. The current annual planting programme, in State forests alone, of approximately sixty thousand acres requires the use of large areas of these types of land, and work has been going on actively since 1919 in such diverse conditions as those afforded, for example, by the Yorkshire moors, the peat-covered Border country, the upland heaths of north-east Scotland, of Wales and of south-west England, and the blanket bog of the north-west of England. In forming their plantations, foresters had little to guide them at first except the existence of one or two relatively small plantations, the history of which had been recorded. They have had to hammer out their own technique. The need for carefully conducted experimental work was early recognized, and the large number of experiments carried out in the west and in the north, covering a wide range of subjects, such as choice of species, methods of planting, ploughing, drainage and the use of fertilizers, has had a marked influence on the course of events.

J. M. B. Brown (Forest Research Station, Alice Holt), in a paper on "The Role of Indicator Plants in Moorland Afforestation", discussed the use of the natural flora of moorlands and heathlands as a guide in the selection of tree species for planting. The vegetation on the ground before planting has been extensively used during the past thirty years for determining what land is plantable and what is unplantable and for allocating tree species to the various sites. Interpreted with discretion, the natural flora may give useful information by indicating which species of tree appears to be suitable to the local conditions of soil and climate. In Great Britain, however, there is, even now, comparatively little evidence which helps to correlate the performance of trees throughout their life-time with the vegetation at the time of planting. The difficulties of the problem have been greatly increased by the use of exotic conifers in moorland afforestation, for many of these trees have been widely used only during the past thirty years and some of them have scarcely been studied ecologically in their native habitats. The natural vegetation may also suggest the kind of difficulty to be expected in establishing trees on the site and the degree to which individual species will be susceptible to these difficulties. Here, there is much more experience which may safely be relied on, but the occasional inconsistencies which occur emphasize the need for caution in making broad generalizations. The character of the vegetation has been little used as a guide in deciding which types of moorland should be ploughed before planting, as the use of the plough has now become general. Nevertheless, an examination of the plant community present before ploughing will usually tell what is likely to succeed it after ploughing and how rapidly the changes will take place. This is important in assessing the competition which the young trees will have to face.

Trees which will ultimately give a good account of themselves on moorland may be very difficult and costly to establish; on the other hand, trees which are comparatively easy to establish may not prove adapted to conditions in later life. Both the long-term and the short-term aspects must be kept in view.

The classification of moorlands for afforestation should not be based wholly on the occurrence of a few familiar and easily recognized dominant plants, which, because of their wide tolerance, may be apt to mislead. Regard must also be paid to the less-conspicuous associates, to notable absentees, to the height, luxuriance and health of the dominants, and to evidence of disturbance by grazing, burning and peat-cutting.

"Recent Work on the Problems of Moorland Afforestation" was discussed in a paper by J. W. L. Zehetmayr (Research Branch, Forestry Commission, Edinburgh), who stated that one of the main functions of sylvicultural research at the present time is to increase the area of 'plantable' land by making it possible to afforest land which is at present classed as 'unplantable'. This may also have the effect of improving production on ground already regarded as suitable for planting. Experimental plantations, made at various times since 1921, have, in many cases, served as pilot schemes which have since been followed by extensive plantations on ground that was originally regarded as of doubtful value for forestry. In other instances, experimental plantations, though tolerably successful, have not yet inspired sufficient confidence for more widespread application of their results; examples of these may be found on deep basin peats and on thinner slope peats in the north-west of Scotland.

In the afforestation of peat, the first consideration is drainage, and drains are now invariably used to provide turves in which the young trees are set in planting. It was shown in early work that the more turf a plant has round about it, the better it grows. The provision of more turf for each plant led to more surface-draining by ditches, but so long as all the work had to be done by hand the economic limit was soon reached. Nowadays the draining plough is used to provide a continuous strip of upturned turf on which planting can be done. This has given satisfactory growth; but the system of equally sized drains, one alongside each row of plants, raises difficulties in subsequent maintenance, while the drains do not run sufficient water to clean themselves. One solution is to use two ploughs, a large plough such as the 'Cuthbertson' to make the main drains, and a lighter, shallower plough, like the 'Begg' or the 'Haddington', to provide material for turf-planting. The use of mechanical methods has decreased the quality of the work, as it is less easy with machines to site the main drains correctly. The Norwegian method of making very large deep drains at wider intervals and of using explosives in their formation is now receiving attention in Great Britain. It may have uses on land where ploughing is impossible.

Draining is not a problem on the heaths, most of which lie in the drier, eastern half of Britain; but ploughing, which is now the standard practice on these sites, leads to the disappearance of surface water which often lies long, while the rupture of the pan allows water to percolate through the soil so that no drains for removing water from the area are necessary. Ploughing has greatly improved the early growth of trees on heathland. The current method of ploughing is to cut a deep furrow every five feet with a heavy plough which breaks the pan and throws up a ridge of spoil. Other methods, such as complete ploughing to a less depth, and the use of a 'tine' plough, are being tried experimentally. An important advance is the introduction of the hydraulic-lift tractor, which greatly increases ease of manœuvring and allows the plough to be lifted over boulders and rock outcrops. On difficult sites it is usual to apply ground mineral phosphate or high-grade basic slag at the rate of 1½-2 oz. to each plant. Recent work by E. M. Crowther has shown that nitrogenous fertilizers improve the growth of newly planted trees on heathland.

On difficult or on marginal sites it is important to use the best 'strain' or 'race' of the tree which is selected for planting. One aspect of this was dealt with by J. A. B. Macdonald (Forestry Commission, Dumfries) in his paper on "The Place of *Pinus contorta* in British Sylviculture". This pine, a native of western North America, has come into prominence lately as a result of its success as a planted tree on poor peat and heathland sites. It has a wide range in North America, along the Pacific coast from Alaska to California, and inland into the Rocky Mountains. With such a range of altitude and latitude it naturally varies, the two extreme forms being recognized as the beach or shore pine, *P. contorta* Dougl. ex Loud, and the inland lodgepole pine, *P. contorta* var. *latifolia* Engelm. The former is a strong-growing coarsely branched tree, with dark green foliage, which throws a comparatively heavy shade; the latter has normally a straighter stem, finer and more open branches, and thinner, yellowish-green foliage. Sylviculturally they have rather different effects.

Various provenance trials of *Pinus contorta* have been planted in different parts of Great Britain, and preliminary assessments of the different plots show that coastal lots from Oregon and Washington grow fastest, while there is a suggestion that, if the whole range of the tree along the Pacific coast is considered, plants from the northern part of this range grow more slowly in Britain than plants from farther south.

With the inland forms, the opposite may prove to be the case. The longest branches appear to grow on trees from the most northerly Pacific coastal origins, while the shortest branches tend to grow on trees from inland regions in the south. Generally there are more branches per whorl on the coastal forms. The coastal trees have shorter needles, averaging 1½ in., while inland forms have needles averaging 2–2½ in. in length; the inland lodgepole pine does not hold its needles as long as the coastal form, on which needles are retained for three years or more. All the trees of coastal origin have completely, or almost completely, killed out the ground vegetation; but very little suppression has been effected by inland forms.

These papers were preceded by an account by James Macdonald (director of research and education, Forestry Commission) of recent developments in forestry nursery technique. The success of a large planting programme depends on a continuous supply of suitable planting stock, and thus the raising of plants in the nursery has always been regarded as of prime importance. Various difficulties have been encountered in running nurseries at high pressure for the provision of young trees, almost entirely coniferous; during the nineteen-thirties, for example, there was a serious diminution in the fertility of many nurseries. One approach to the solution of this problem was made by the late Dr. M. C. Rayner, who established at Wareham, in Dorset, a nursery which made an important break with established practice. Instead of using an agricultural soil, Dr. Rayner set to work on a piece of uncultivated heathland and, by shallow cultivation, subsoiling, and a liberal use of composts, produced successive crops of seedlings much larger than had ever been raised before. Her technique, with various modifications, was widely used elsewhere, and a considerable proportion of the seedlings produced to-day are grown in 'heathland' nurseries. These nurseries, when properly sited and managed, are remarkably free from weeds, and the saving in weeding costs is an important item to be set off against the expense of the other operations. This technique did not solve the problems of the ordinary forest nursery; it avoided them. They were approached, however, from another side; by means of partial soil sterilization, with steam, with formalin and with other chemicals, combined with appropriate fertilizer treatment, nursery soils which had been producing very poor seedlings began to yield plants as good as those in heathland nurseries, while there was also a substantial reduction in weeding. The complex of factors involved in this and in other nursery processes is being studied by a committee which was set up by the Forestry Commission in 1944, under the chairmanship of the late Prof. F. T. Brooks, and on which Drs. E. M. Crowther and A. B. Stewart are active members. It has been found possible to raise with fertilizers seedlings as good as those produced with the aid of compost or sterilization; it has also been established that many conifers, and particularly Sitka spruce, are highly sensitive to lime in the nursery and that some of the trouble in the established nurseries was due to injudicious liming. Because it is possible to raise seedlings which can be handled at the end of their first year, it has been possible to use many more two-year-old transplants in moorland afforestation. These are less costly than the three/four-year old plants formerly used.

The prospect of effective weed-control in seed-beds has been brightened by the use of mineral oils applied before the tree seedlings emerge, while other directions in which research is proceeding are in the use of overhead irrigation and in the attempt to raise two or three successive crops of seedlings in a season with the help of bottom heat.

NEWS and VIEWS

Physiology in the University of London: Prof. Geoffrey Harris

Prof. Geoffrey Harris, who has been appointed to the Fitzmary chair of physiology in the University of London, is known for his work on the control of the pituitary gland. This chair, of which he is the first holder, is named after Simon Fitzmary (1492), the founder of Bethlem Royal Hospital; it is attached to the Department of Neuro-Endocrinology of the Maudsley Hospital. Prof. Harris was first trained in anatomy and medicine in Cambridge, and, after qualifying at St. Mary's Hospital, London, became in 1940 demonstrator and later lecturer in anatomy at Cambridge; in 1948 he was appointed lecturer in the Department of Physiology. His research work has been on the anatomy and physiology of the pituitary gland and on the control of pituitary secretions by the nervous system. In his recent work he has modified the technique of implanted electrodes and placed small secondary coils under the scalp with an electrode placed in various sites near the supra optic nuclei. By using a primary coil surrounding the animal, he was able to produce endocrine effects on urine flow, oestrus, etc., without otherwise disturbing the animal. He has shown the existence of a hormonal link, carried by a system of portal vessels, between the nervous and secretory structures. The pituitary forms the main link by which external events affect the endocrine glands via the nervous system, and this clarification of how this is effected helps in our understanding of both. His work is characterized by great skill in difficult operative techniques and in masterly grip of the physiological and anatomical problems of his chosen field. Prof. Harris's many friends will be glad that in his new post he will be able to devote himself almost entirely to research in this rapidly developing field, in which he has done so much to clarify our ideas during the past fifteen years.

H. G. Smith (1852–1924): a Pioneer Australian Chemist

An interesting centenary has recently been observed in Sydney, marking the birth on July 26, 1852, of Henry George Smith, a pioneer worker on the chemistry of the Australian flora. Smith was born at Littlebourne, in Kent, and emigrated to Australia in 1883. He amplified his scanty scientific training while holding a humble post at the Sydney Technological Museum, and in 1891 published his first original paper, announcing the discovery of barytes in the Hawkesbury sandstones at Sydney. In 1895 he became mineralogist at the Museum. An ensuing paper on eucalyptus kinos and the occurrence of eudesmin, published in collaboration with J. H. Maiden, the botanist, heralded a long series of original contributions to the chemistry of Australian essential oils, exudations and other indigenous plant-products. In 1899 Smith became assistant curator and economic chemist in the Museum, and most of his work on the chemistry of the Australian flora was carried out in collaboration with R. T. Baker, curator and economic botanist in the Museum. Their *magnum opus*, "A Research on the Eucalypts, especially in regard to their Essential Oils", was published first in 1902 and again, in an extended form, in 1920.

Upon his official retirement in 1921, Smith became associated with the then recently founded Department of Organic Chemistry in the University of Sydney, where he pursued further work, partly in collaboration with Prof. John Read, on the chemistry of some of the substances, notably the eucalyptus ketone, piperitone, that he had isolated in earlier researches. Smith and Read had previously collaborated in an investigation of the so-called 'marine fibre' of *Posidonia australis*; the results of this lengthy research were issued in 1919 as one of the early publications of the Institute of Science and Industry of the Commonwealth of Australia. One of Smith's last investigations dealt with the possibilities of utilizing Australian wood fibres in paper-making. Altogether, Smith published more than a hundred original contributions to chemical science; sixty-two appeared in the *Proceedings of the Royal Society of New South Wales*, of which Smith was a modest but much-esteemed member. A meeting of the Sydney University Chemical Society held last August was devoted to terpene chemistry, with special tributes to Smith's life and work. Many of his original isolations, papers and photographs were displayed, and addresses were given by Prof. A. J. Birch, of the University of Sydney, and Mr. W. J. Dunstan, of the New South Wales University of Technology.

J. N. Langley, F.R.S. (1852–1925)

John Newport Langley, whose signature is writ large in the history of the sympathetic nervous system, was born at Newbury a century ago, on November 2, 1852. In his second year at Cambridge, his interest in biology and physiology was aroused by Michael Foster, and he obtained a first class in the Natural Sciences Tripos in 1874 and three years later an open fellowship at Trinity College. His early research on the action of pilocarpine on the frog's heart was followed by a meticulous study, taking fifteen years, of the process of secretion in the mammalian salivary gland, in the course of which he distinguished between the 'loaded' and the 'exhausted' states of the gland. Foster had been made professor of physiology in 1883, and Langley, on being appointed in the following year as university lecturer in histology, became his assistant, succeeding him in the chair in 1903. During 1890–1906, helped by Hugh Anderson and W. H. Gaskell, Langley threw a flood of light on the sympathetic nervous system, his researches being a landmark in the history of physiology. He defined the autonomic system as an efferent system in 1903, and in 1921 published a book on the subject. He was working on the mechanism of excitation of cells when the outbreak of the First World War caused him and his depleted staff to pursue investigations of greater national urgency, such as the trophic changes in muscle and nerve following injury. In 1894 Langley paid off the debt which had long burdened the *Journal of Physiology*, and continued as owner and editor until his death. He was elected to the Royal Society in 1883 and vice-president in 1904. He died of pneumonia on November 5, 1925.

Regional Scientific Advisers for Civil Defence

The organization of regional scientific advisers for civil defence in Great Britain, which has been set up by the Home Office, is now virtually complete. Many of the leading scientific men of the country have responded to the appeal of the Home Secretary and the Secretary of State for Scotland, and are giving their advice and assistance in this vital department of the country's defence organization. In each of the eleven regions into which England and Wales are divided for civil defence purposes, a group of these scientific men has been appointed, and similar appointments have been made in Scotland by the Scottish Home Department. It is understood that the Government of Northern Ireland will also shortly appoint scientific advisers. These scientific advisers serve in an honorary capacity in time of peace, and are accredited to the staff of the Chief Scientific Adviser of the Home Office, Whitehall, London, S.W.1. They also give their advice and assistance independently to the civil defence authorities in their own regions. An important step has thus been completed. In effect, a panel of scientific consultants has been formed so that the best scientific thought and experience can be applied both nationally and regionally to the problems of civil defence. At the present time the regional scientific groups are giving valuable assistance in the formation and training of the technical reconnaissance units of the Civil Defence Corps, the officers of which are required to have university qualifications or be members of the professional scientific institutions. The regional scientific advisers are arranging and supervising courses of scientific instruction for them at the universities in the regions, particularly in the physics of atom warfare and the chemistry of the war gases. The contacts between the advisers and the professional institutions are most advantageous; and the institutions themselves have already volunteered their help in directing the attention of their members in the regions to the need for qualified men and to the importance of offering their services.

The several regions, with their centres and senior and other scientific advisers, are as follows: *Northern Region* (*Newcastle upon Tyne*): Prof. W. E. Curtis, Prof. G. R. Clemo, Dr. G. H. Christie; *North Eastern Region* (*Leeds*): Prof. F. W. Spiers, Prof. W. Bradley, Prof. W. Sucksmith; *North Midland Region* (*Nottingham*): Prof. L. F. Bates, Dr. D. O. Jordan, Prof. L. Hunter; *Eastern Region* (*Cambridge*): Dr. B. C. Saunders, Mr. E. S. Shire, Dr. E. N. Fox; *London Region*: Sir Charles Ellis, Prof. W. V. Mayneord; *South Eastern Region* (*Tunbridge Wells*): Brigadier R. A. Bagnold, Prof. D. H. Hey, Dr. F. C. Champion; *Southern Region* (*Reading*): Dr. H. W. Thompson, Prof. R. W. Ditchburn, Prof. A. N. Black; *South Western Region* (*Bristol*): Prof. W. E. Garner, Prof. S. H. Piper; *Wales* (*Cardiff*): Prof. W. N. Thomas, Prof. F. Llewellyn Jones, Dr. S. T. Bowden; *Midland Region* (*Birmingham*): Prof. H. W. Melville, Prof. P. B. Moon, Prof. J. R. Squire; *North Western Region* (*Manchester*): Prof. E. R. H. Jones, Dr. G. D. Rochester, Prof. C. E. H. Bawn; *Scotland*: Sir Edward Appleton, Prof. N. Feather, Prof. J. W. Cook, Prof. R. V. Jones, Prof. D. H. Everett.

Oil Pollution of the Sea

A MEETING of the Permanent Committee on oil pollution which was set up in June 1952 was held at the House of Commons on October 23, under the chairmanship of the Earl of Ilchester. Representatives of the following organizations which constitute the Committee were present: Association of Sea Fisheries Committees of England and Wales, Council for the Preservation of Rural England, International Committee for Bird Preservation, Royal Society for the Protection of Birds, Universities Federation for Animal Welfare, County Councils Association, Association of Municipal Corporations, Urban District Councils Association, Rural District Councils Association and the General Council of British Shipping. It was decided that the official name should be the Co-ordinating and Advisory Committee on Oil Pollution of the Sea (*Secretary*: Miss Phyllis Barclay-Smith, International Committee for Bird Preservation (British Section), c/o British Museum (Natural History), Cromwell Road, London, S.W.7). The meeting expressed gratification at the setting up by the Minister of Transport of a Government committee to investigate the problem, and it was agreed to offer this committee every assistance and co-operation, particularly with regard to providing factual evidence. The urgency of the problem was again stressed and the serious situation with regard to the pollution of small harbours was emphasized.

The clerk of Truro Rural District Council reported the results of an experiment carried out on St. Agnes Beach, Cornwall, during June 1–September 8, 1952. During these hundred days the beach, which is a small one of 160 yards in length at highwater mark, was cleared of oil deposits, which were weighed. The results showed that more than fifty-seven hundredweights of waste oil were washed up during this period, that is, an average of more than 64 lb. per day.

Greenwich Mean Time

THE practice at the Royal Observatory, Greenwich, of dropping the Time Ball, the symbol of Greenwich time throughout the world, was resumed at 1 p.m. on October 26. The Time Ball is a dull red sphere, 5 ft. in diameter; it is part of the Wren Observatory building and was erected for the purpose of enabling masters of vessels proceeding down the Thames to adjust their chronometers. The Time Ball is raised half-way up a mast, on which it slides, at five minutes to one, hauled to the top at two minutes to one, and released electrically on the hour. It was the earliest means of making Greenwich mean time known to the public, but the system has now been superseded for all practical purposes by the six pips broadcast at fixed times by the B.B.C. and by the speaking clock operated by the G.P.O. The Ball was operated continuously from 1833, when first installed, until the Observatory was evacuated during the Second World War. Its operation was temporarily resumed at the start of the Festival of Britain, but it is now intended to continue dropping it as long as members of the Observatory staff remain at Greenwich. Instruments of purely historical interest, such as the Time Ball, will remain at Greenwich.

Meteorology and Agriculture

SIR ROBERT WATSON-WATT, in his presidential address in 1951 to the Royal Meteorological Society, suggested a number of steps which might be taken to match meteorology to man's needs. One was for the Society to set up 'Interest Groups' for such subjects as agriculture and horticulture, fishing, education, transport and engineering. This suggestion has led to the initiation by the Royal Meteorological Society of its first Interest Group, on meteorology and agriculture and horticulture, under the leadership of Dr. G. L. Hogben. This development will be marked on the occasion of the second annual dinner of the Society on November 27, to be held in London, when the guest of honour will be Sir James Scott Watson, chief scientific and agricultural adviser of the Ministry of Agriculture and Fisheries and director general of the National Agricultural Advisory Service. He will be supported by distinguished representatives of agricultural science and practice and of meteorology.

Seismic Refraction Shooting in the Atlantic

M. N. HILL and J. C. SWALLOW have developed a method of seismic refraction shooting at sea using hydrophones at a depth of 100 feet below the surface of the sea, connected with sono radio buoys at the surface. Depth-charges exploded at a depth of 900 ft. send compressional waves through the sea and the rocks of the sea-bed. These *P*-waves are received on the hydrophones, and the records are transmitted to the ship by signals from the sono-radio buoys. Thus only one ship is necessary for the work. Experiments to test the method and to explore the sea-bed were carried out by Hill and Swallow from the Ocean Weather Ship *Weather Explorer* during August 1949, while the ship was occupying her routine position for meteorological observations at lat. 53° 50′ N., long. 18° 40′ W. The results have been written up by Hill alone (*Phil. Trans. Roy. Soc.*, A, No. 890, 244, 561; June 17, 1952; 7*s*. 6*d*.). The depth of water in this area of the eastern Atlantic is approximately 2,400 m., and below this Hill and Swallow found, as the result of the experiments, unconsolidated sediments of thickness 1,900–3,000 m. The velocity of *P*-waves in the sediments varied from 1·5 km./sec., nearest the water, to a limiting value of 2·5 km./sec. at depth. Below the unconsolidated sediments they also deduced the presence of crystalline rock to a depth of 2·7–3·4 km., through which *P*-waves travelled at 5·0 km./sec. Below this, to an unknown depth, they deduced the presence of rock which transmitted *P*-waves at 6·3 km./sec.

Overseas Information and Broadcasting Services

REPLYING to a question in the House of Commons on October 22, Mr. H. A. Nutting, Under Secretary, Foreign Office, said that the following committee has been set up to inquire into the overseas information and broadcasting services: Lord Drogheda (chairman), Sir R. Bruce Lockhart, Mrs. Mary Stocks, Mr. J. W. Platt, Mr. Gervas Huxley, Mr. Donald McLachlan, Mr. Victor Feather, and Mr. Laurence Heyworth. The terms of reference are: "To assess the value, actual and potential, of the oversea information work of the Foreign Office, Commonwealth Relations Office, Colonial Office, Board o Trade, and Central Office of Information; the External Services of the British Broadcasting Corporation; and the work of the British Council; to advise upon the relative importance of different methods and services in different areas and circumstances; and to make recommendations for future policy".

The Night Sky in November

FULL moon occurs on Nov. 1d. 23h. 10m., U.T. and new moon on Nov. 17d. 12h. 56m. The following conjunctions with the moon take place: Nov. 2d. 15h., Jupiter 7° S.; Nov. 15d. 06h., Saturn 7° N.; Nov. 19d. 03h., Mercury 2° N.; Nov. 20d. 11h., Venus 1° N.; Nov. 22d. 05h., Mars 0·2° S.; Nov. 29d. 17h., Jupiter 7° S. Mercury, an evening star, is too close to the sun for favourable observation and is in inferior conjunction on November 30. Venus is a conspicuous object in the western sky, setting about 17h. 55m. during the first part of the month and at 18h. 20m. on the last day; its stellar magnitude is − 3·5, and more than three-fourths of its illuminated disk is visible. Mars sets at about 20h. 05m. throughout November, stellar magnitude 0·9; but as its south declination is considerable, it does not rise very high above the horizon. Jupiter is visible throughout the night, setting in the morning hours at 7h. 40m., 6h. 30m. and 5h. 20m. on November 1, 15 and 30, respectively, and is a conspicuous object, stellar magnitude − 2·4, in the constellation of Aries; on November 8 the planet is in opposition to the sun. Saturn is a morning star, its times of rising being 5h. 10m., 4h. 20m. and 3h. 20m. at the beginning, middle and end of the month, respectively, stellar magnitude 1, and is easily recognized a little north of Spica. Occultations of stars brighter than magnitude 6 are as follows (observations being assumed to be made at Greenwich): Nov. 4d. 0h. 23·1m., χ Taur. (*R*); Nov. 8d. 1h. 57·8m., μ Canc. (*R*); Nov. 23d. 19h. 22·9m., 42 Capr. (*D*); Nov. 30d. 17h. 28·5m., η Taur. (*D*); Nov. 30d. 18h. 21·7m., η Taur. (*R*). *R* and *D* refer to reappearance and disappearance, respectively. The Andromedids and Leonids are due about November 14 and 16, respectively, but these meteor showers are now very weak and comparatively few meteors from them have been seen in recent years.

Royal Society of Edinburgh: Officers for 1952–53

The following were elected officers and Members of Council of the Royal Society of Edinburgh at the annual statutory meeting held on October 27: *President*, Prof. James Kendall; *Vice-Presidents*, Prof. E. T. Copson, Prof. J. H. Gaddum, Sir Robert Muir, Prof. James Ritchie, Prof. R. C. Garry, Prof. W. M. Smart; *General Secretary*, Dr. J. E. Richey; *Secretaries to Ordinary Meetings*, Prof. J. Norman Davidson, Dr. John E. Mackenzie; *Treasurer*, A. W. Young; *Curator of Library and Museum*, Dr. Douglas Guthrie; *Councillors*, Prof. J. F. Allen, Prof. A. Murray Drennan, Dr. E. Wyllie Fenton, J. M. Ross, Prof. C. M. Yonge, Prof. Norman Feather, Sir Godfrey Thomson, Dr. D. P. Cuthbertson, Principal H. B. Nisbet, Prof. T. C. Phemister, Dr. J. B. Simpson, Prof. Meirion Thomas.

Announcements

Dr. W. G. Penney, O.B.E., F.R.S., chief superintendent of the Armament Research Department, who has been responsible for the design and testing of the British atom bomb, has been promoted to be knight commander of the Civil Division of the Order of the British Empire (K.B.E.).

Lord Radnor, who has been a member of the Forestry Commission since 1951, has been appointed chairman of the Commission in succession to the late Lord Robinson, who died on September 5.

The 119th meeting of the American Association for the Advancement of Science will be held in St. Louis, Mo., during December 26–31. Besides the individual sessions of the eighteen sections of the Association, more than forty societies affiliated or associated with the Association will be concurrently holding meetings. Further information can be obtained from the director of public information, Sidney S. Negus, Medical College of Virginia, Richmond, Va.

The British Scientific Instrument Research Association is holding open days at its laboratories at 'Sira', Southill, Elmstead Woods, Chislehurst, on November 5 and 6.

An exhibition of Spanish scientific books has been arranged at the Science Museum Library, London, S.W.7, and will be open to the public during November 6–20.

A World Congress of Medical Practitioners for the Study of the Actual Conditions of Life, which was to have been held in Montecatini during October 16–18 (see *Nature*, June 28, p. 1085), did not take place owing to the refusal of the Italian Government to authorize the meeting. The Congress authorities hope to hold it some time during the first half of 1953. Further information can be obtained from the secretary, Dr. C. Massenti, Corso Trieste 65, Rome.

An exhibition entitled "Training for Industry", showing the work of the City and Guilds of London Institute, will be on view at the Goldsmiths' Hall, Foster Lane, Cheapside, London, during November 4–14, and will be inspected on November 3 by H.R.H. the Duke of Edinburgh, president of the Institute. The exhibition has been arranged in connexion with the Institute's yearly meeting, and among the features to be seen will be models of scientific and engineering equipment, including a supersonic wind-tunnel, from the City and Guilds College, South Kensington; students' work in fine arts and crafts from the City and Guilds Art School, Kennington; and a pictorial presentation of the work of the Institute's Department of Technology which covers nearly two hundred subjects.

The Meldola Medal, which is the gift of the Society of Maccabæans and is normally awarded annually, is being offered for award early in 1953 to the chemist who, being a British subject and less than thirty years of age on December 31, 1952, shows the most promise, as indicated by his or her published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31. Communications should be addressed to the President, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1, the envelope being marked "Meldola Medal".

Sir George Beilby Memorial Fund awards, which are considered by administrators representing the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Metals, are made at intervals to British scientific research workers, preference being given to investigations relating to the special interests of Sir George Beilby, including problems connected with fuel economy, chemical engineering and metallurgy. In general, the awards are granted to younger men and women for original work done over a period of years. Awards may be made early next year, and the administrators request that their attention be directed, not later than December 31, to outstanding work of the nature indicated. All communications should be addressed to the Convenor of the Administrators, Sir George Beilby Memorial Fund, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

PROBLEMS OF THE SMALL FARM

THE three papers covering the problems of the small farm, given at Belfast on September 8 to Section M (Agriculture) of the British Association, differed in scope so widely that it was difficult at first to see how they fitted together; but on examination, it was possible to see a pattern which at least indicated some of the problems facing small farmers in the United Kingdom, without providing a ready-made solution for them.

Mr. Ronald Ede, agricultural attaché for Denmark, described the agricultural system in Scandinavia and the Low Countries. This account was particularly interesting because, although the average size of farm holdings in these countries is well below that of Great Britain, it is an accepted fact that the farming efficiency is high, and high-quality farm produce is exported at competitive prices in the world market. The second speaker, Mr. A. Cromie, a farmer in Northern Ireland, described his own farm—a typical small one in a country where the average size of farm is small—and gave his views on the problems facing farmers such as himself. The importance of his paper lay in the fact that he is a very progressive farmer. Finally, Mr. W. H. Cashmore, director of the National Institute of Agricultural Engineering, Silsoe, related the problems of mechanization to the size and type of farm and suggested that attention to organization, careful selection of equipment and further work on farming techniques would play their parts in extending the benefits of mechanization to the smaller farms.

In describing Scandinavian agriculture, Mr. Ede stated that nearly all land is owned by the farmers, but there is rigid government control of the size of small-holdings. Although the minimum size is five acres, the average is less than forty acres, and the tendency during the past thirty years has been to reduce both the number of large and small farms, and so raise the number of farms of average size, amalgamation of farms being prohibited. The labour is mostly family labour, and the majority of farms run on a mortgage at a low rate of interest. A smallholder with £250–500 capital can borrow up to £3,200, and the average level of borrowing is about £1,300.

The standard of living on the Danish farm is low compared with that in Britain, and smallholders are not replacing themselves because of the difficulties of finance. Many of the sons of smallholders move into industrial employment, the keenest demand for small farms coming from the sons of the medium-sized farms.

There is no State advisory service in Denmark, but advice reaches the farmers through the Smallholders' Association. Mr. Ede did not mention anything of special note about the cropping, except that there is a marked increase in fodder beet and a steady rise in fruit growing. The larger farms tend to grow the cereals for feeding-stuffs, and on the smallholdings grassland predominates.

Some machines, particularly the special and expensive implements, are handled on a co-operative basis. The standard of machinery at the homestead for handling cattle-food is high. The main features of Danish smallholdings are: small acreage (by British standards), good buildings that are well equipped, and dependence on borrowed capital. Even in Denmark there is some concern about the level of borrowed money, and it is realized that a fall in world prices would cause difficulties. In the discussion on this paper the mortgage position was the main topic. The general opinion was that the amount borrowed was high and, while it might be sound policy to raise money for current expenditure, it was risky to use borrowed capital for such items as machinery and buildings.

Mr. Cromie's farm is 37½ acres, of which 29½ is arable, and he rents a further 34 acres. His cropping is varied and includes small acreages of fodder crops such as marrow stem kale, fodder beet and arable silage; he also grows cash crops such as potatoes, ryegrass and oats, for seed.

The livestock consists of twelve Friesian cows and their followers, five sows and all their progeny, plus thirty to forty extra pigs each year, and some poultry. It was obvious that his stocking and production was well above average. The following examples illustrate the planning to raise the total output: the tractor had been equipped to do all the work, to the total exclusion of horses, thereby making it possible to carry two more cows; an analysis of the soil from various parts of the farm had indicated deficiencies which, when corrected, made it possible to carry more stock with an appreciable increase in the milk yield; a proportion of the grassland is ploughed out and reseeded each year to keep up the quality of the grass; silage-making is practised to conserve grass; and an electric fence is used for strip or controlled grazing.

Mr. Cromie confirmed the view that the production per acre can be higher on a small farm than a larger one because of greater personal attention and supervision. He was convinced that the output could be increased by 100 per cent if the results of agricultural science could be put into practice. At the present time a good deal of scientific work does not reach the small farmer. Quite often, improved techniques required additional capital outlay, and Mr. Cromie stated that the greatest handicap to progress was the large amount of capital needed, especially for reconstruction of buildings.

Great interest was aroused by the statement that the standard of knowledge on the farm will have to be raised. In the discussion, Mr. Cromie explained that farmers are taking an increasing interest in the management of a farm and the application of scientific work, but that the farmer is often too tired at night to go to lectures, discussions, etc., after a long day of toil. He thought that there is need for greater effort in spreading knowledge of scientific and experimental work, and suggested that demonstration farms would help.

Mr. Cromie confirmed that a farmer and his wife can make a fair living from about thirty-five acres in Northern Ireland, but he himself was strongly in favour of extending the area farmed by a further thirty acres; this justifies the services of a hired man and makes possible an increase in livestock. He admitted that in practice the high rental of the extra land and the labour cost offset most, if not all, the extra income.

In the discussion it was suggested that specialization on a few crops might increase the overall output per acre, and the idea of installing a small grass-drier to provide concentrated food for the dairy cattle and for sale was put forward. The case against 100 per cent grassland on the small farm is that arable land helps to keep the farm clean, and provides some cash crops such as potatoes and seed corn as well as by-products for livestock.

Mr. Cromie is without mains electricity, which is essential for a highly mechanized dairy and many of the appliances which support a 100 per cent grassland farm. In considering how far the use of machinery could assist the small farm, Mr. Cashmore stated that as the size of farm decreases below two hundred acres there is a marked upward trend in the capital invested in machinery per acre. His paper dealt with farms in the 50–150 acres class, on the assumption that below this level some specialization in cropping was necessary and so was outside the scope of this paper.

An analysis of capital invested in machinery and annual cash returns indicates that the greater use of machinery raises the yield rather than replaces regular labour. The margin of profit from increased mechanization is slender and very dependent on sound organization and proper maintenance. Even in the 50–150 acres class, capital expenditure on machinery increases as the size of holding decreases, but is justified by the higher returns per acre due to personal supervision and attention to detail.

In discussing how far expenditure on machinery could be kept down, Mr. Cashmore quoted from field surveys and investigations to show that in a number of cases the main advantage of a specialized machine is that it enables men to work a long day without undue fatigue. For short periods there is a slightly higher demand for labour ; but the overall cost of the operation is no higher. On these grounds it could be argued that the small farm would gain nothing by purchasing these machines. The limitations of the co-operative use of machinery were stated ; but where suitable contractor service is not available, there are possibilities in local farmers' co-operative societies for the use of certain expensive equipment. This system is already being employed in England for cereal harvesting and grass drying, and might be extended to ditching, hedge cutting, dung loading, etc.

Considerable emphasis was placed on better techniques and improved organization, and investigations were quoted to show that the efficiency of organization has a greater effect on the cost of a process than the design of the equipment. Commenting on general design, Mr. Cashmore stated that the small farm does not require scaled-down tractors or implements except in the case of barn machinery, which can be designed to run automatically provided electricity is available and the buildings are in good order. Already satisfactory equipment for the small farm has been devised, examples being milking machines and platform grain driers. It is possible that many more modifications or new developments would be helpful, but these must be related to technique investigations.

The discussion supported these views and emphasized the need for detailed studies to reveal whether the various problems could be solved by improved techniques, improvisation or new machines. It was thought that on the small farms the field equipment would have to be kept as simple as possible, with marked development of machinery for handling cattle food at the homestead.

In conclusion, the problems facing the small farmers are : shortage of capital, lack of knowledge on scientific work, poor farm buildings, and, in some cases, the wrong machinery. All these problems are interrelated, and, provided the size of holding is not less than 50–75 acres for general farming, it is reasonable to expect progress in the future.

W. H. Cashmore

CHEMISTRY IN ABERDEEN

By Prof. R. M. Barrer

Chemistry was one of the first sciences to develop as a university study. In part for this reason, but still more because of its intrinsic interest and great practical value, the subject now attracts many students. University departments, often designed long ago to house smaller numbers, have in many centres become inadequate and outmoded. It is a feature of recent university development in Britain that serious efforts are being made to remedy this situation by rebuilding or by rehabilitating and extending existing chemistry departments. In Aberdeen, the University is now seeing the completion of a building first contemplated more than thirty years ago, and commenced in January 1949. The subject of chemistry has been removed from Marischal College, where it had been taught since the union of the two original Universities of Aberdeen in 1860, and has been rehoused on a site near the historic buildings of King's College. The new building was opened by Sir Robert Robinson on September 17. The newness of the department may render a brief description of the layout and facilities of interest to scientists and others concerned in the design of science departments.

The building has been constructed in the form of a cross. Four floors are devoted to chemistry, and a final floor to soil science and agricultural biochemistry, both subjects closely allied to chemistry and of considerable significance to the rich agricultural industry of Aberdeenshire. Each is under a separate head. All floors are served by a central staircase, and by subsidiary stairs at the end of the south wing. In addition, the building contains two lifts, of which one is designed for carrying goods and equipment. The building is a granite structure, the granite of several blending hues having been taken from six different quarries.

The lower ground floor of the building contains the main chemical and apparatus stores, mechanical, glassblowing and electronic workshops ; a refrigerated room operating at adjustable temperatures down to − 10° ; and the electron microscope. There is in addition some research accommodation on this floor. In the east wing of the ground floor is situated the large elementary chemistry laboratory, with two balance rooms, one at each end. Associated preparation and subsidiary store rooms run into the south wing, which also contains research and staff rooms and a lecture room. This room is served by a large preparation room which also serves the main lecture theatre in the west wing. The theatre is excellently appointed and holds about 220 students. In the north wing are the main entrance hall, and large cloakrooms. Additional cloakrooms are available on every floor.

The first floor houses in the east wing the inorganic teaching laboratory with associated preparation and balance rooms. There is also a room especially provided for electrochemical work, and an inorganic research laboratory. In the west wing is a large research laboratory, and in the north wing a laboratory specially designed for larger scale chemical and physico-chemical operations. There is fume extraction from this room, which can be general or else can be concentrated at any desired point. In the same wing are a departmental library and staff room and further research laboratories. The south

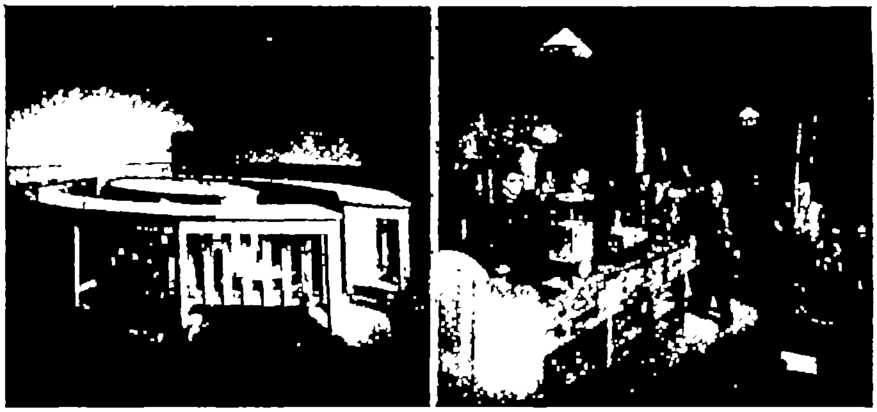

Fig 1 Chemical laboratories at Aberdeen (left) for medical students before 1896, (right) for science students about 1896

wing houses the main chemistry library, an X-ray room, staff rooms, the professor's research laboratory and a third lecture theatre. The second floor contains, in east and west wings respectively, the organic and physical chemistry laboratories, each with associated balance room, preparation room and subsidiary store room. The west wing also contains research laboratories and two well-equipped dark rooms, one for staff and the other for student use. The north wing contains five optical cubicles associated with the physical chemistry teaching laboratory, an electrical instrument store and two constant temperature research laboratories. The south wing contains a laboratory for microchemical analysis and six additional research laboratories. On the third floor of the building one moves into the domain of soil science and agricultural biochemistry. These subjects share a teaching laboratory and preparation and balance rooms in the north wing. Other accommodation provided includes staff rooms, workshop and store, research laboratories for staff and post-graduate students and an advanced teaching laboratory. An instrument room, optical cubicle, map room and museum, nitrogen room, dark room and tutorial room are also provided.

Teaching laboratories and lecture rooms are provided with plenum air as well as general air extraction. All research laboratories have high- and low-level extract from fume-cupboards. In the organic and inorganic laboratories, bench extract is also provided throughout. Research laboratories are designed with the view of maximum interconvertibility for use in any of the three branches of chemistry. Services include high-pressure air, and in some rooms vacuum, in addition to the usual gas, water and electricity supplies. Distilled water is piped from a central unit and also hydrogen sulphide. Many of the research laboratories contain, in addition to several sets of wall services, a complete set of services centrally placed at floor-level and accessible by removing a floor panel. All floors in research and teaching laboratories are sloped to drainage points so that water on floors is removed with minimum difficulty. Research laboratories are of several sizes capable of accommodating from one to four research workers.

Chemistry has advanced steadily within the University of Aberdeen, and the present big step forward emphasizes the high esteem in which the profession of chemistry is held. The first chair of chemistry in Scotland was occupied in Aberdeen in 1793 by George French, surgeon and chemist, although some instruction on the subject was given considerably earlier. While on one hand the cultural value of chemistry was acknowledged remarkably early within the Universities of Aberdeen, on the other

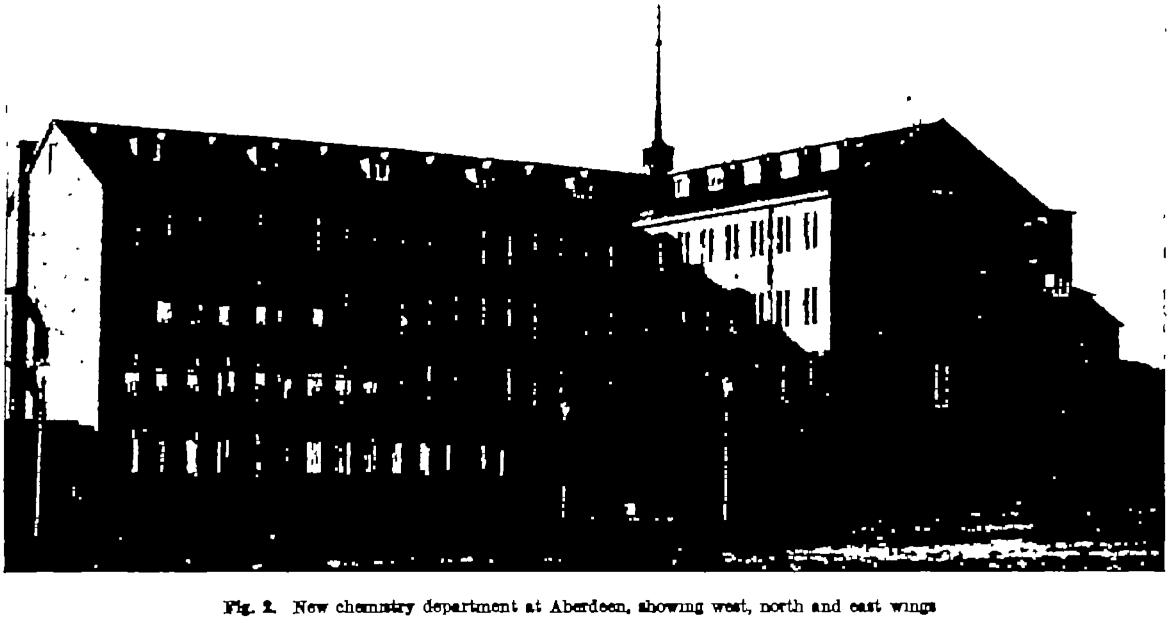

Fig. 2. New chemistry department at Aberdeen, showing west, north and east wings

hand, over all this earlier period no great efforts were spared for research. It was not until Carnelly (1888–90) and Japp (1890–1914) occupied the chair that it was considered particularly necessary for teachers of chemistry to try to extend the boundaries of the subject. Even with the growth of a new attitude, progress in research was not rapid. However, enthusiasm for original investigation was carefully fostered by later occupiers of the chair. There is now a vigorous research school, and the new building reflects the attitude that research as well as teaching is a vital part of any balanced university department. Three photographs are reproduced in this article which indicate the revolution in the provision made for chemistry over the past sixty years. The first photograph shows the chemical laboratory for medical students prior to 1896 and the second the chemical laboratory for science students at about the same time; both are reproduced by kind permission of Prof. A. Findlay, from his book "The Teaching of Chemistry in the Universities of Aberdeen" (Aberdeen University Studies, No. 112). The third photograph is of the west, north and east wings of the chemistry department of 1952. The subject is a forward-looking one where past triumphs are ever likely to be overshadowed by future achievements on a scale still more grand. Nevertheless, there is great interest in looking back and retracing paths, both scientific and personal, trodden by chemists of bygone generations. Such retrospect is bound to emphasize the mounting tempo of science, with all the responsibilities it brings.

THE UNIVERSITY OF CEYLON

By Sir IVOR JENNINGS, Q.C.

Vice-Chancellor

On October 6, the University of Ceylon moved 851 students, of whom exactly 300 were women, from Colombo to Peradeniya, near Kandy. They included all the students in oriental studies, arts and laws and the senior students in agriculture and veterinary science. The Faculties of Science and Engineering will move when their buildings are ready. The Medical School will remain in Colombo; but it is proposed to establish a second medical school in Peradeniya by 1960.

The 851 students include 27 Buddhist monks, who are housed in a University bungalow pending the erection of a monastery by the University Sangharama and Vihare Trust. The other 824 students are housed in five halls of residence. These halls are built on the principle of one student to each room; but since three halls—housing 490 students—will not be ready until 1953, there are usually two students in each room. The cost of residence is Rs. 630 (£46) per annum, and there are no tuition fees for Ceylonese students. Even so, about one-third of the students are subsidized, the University paying the whole or a part of the residence fee.

The present University Park contains 300 acres; but the land vested and to be vested in the University covers 3,000 acres. It includes a tea estate of 1,100 acres which is being converted under a ten-year plan into a timber estate. It also includes an experimental farm of 650 acres (of which 240 acres are cultivable) which is at present used as a School of Agriculture but will be transferred to the Faculty of Agriculture in 1953. This area of land stretches up the valley of the Mahaweli-Ganga for two miles, enclosing the headquarters of the Government Department of Agriculture and the Royal Botanic Gardens.

For seven years in the fourteenth century Peradeniya was the capital of the Sinhalese monarchy. When the capital was moved down the river to Kandy, Peradeniya became a royal garden. Under British rule a small portion (140 acres) became the Royal Botanic Gardens, while the remainder was put first under coffee and sugar and then under tea and rubber. The land receives both monsoons and therefore about 100 in. of rain a year. This creates a luxuriant tropical vegetation, which supports a remarkable fauna. Twenty-six varieties of birds have been identified from the Lodge, without using binoculars. Some ornamental trees were left by the superintendent of the tea estate; but planting was begun in 1942 and is continuing as areas are taken over under the landscape scheme. The climate is equable, for the buildings are between 1,600 and 1,700 ft. above sea-level.

This magnificent valley, framed by the great Hantane Ridge (4,500 ft.) from which the University draws its water supply, is one of the most beautiful university sites in the world. The layout was planned by Sir Patrick Abercrombie and Mr. Clifford Holliday, while the building plans were drawn by a Sinhalese architect, Mr. Shirley d'Alwis, who died of a heart attack two weeks before the students came into residence. Great care has been taken with the architecture of this central group, ancient Sinhalese motifs, mostly of the Polonnaruwa period (A.D. 1000–1200), being adapted to modern buildings. The long and narrow Senate Building, for example, is raised on granite pillars like the Brazen Palace at Anuradhapura, though the weight is carried by good English steel. The canopy of the University Theatre is supported by carved granite pillars, while the massive doors, made of Ceylon teak, are carved in Embekke style. There is, too, a huge 'moonstone', six feet in diameter, carved out of a solid block of granite in the style of the giant moonstone at Anuradhapura. In the Senate Building, Hilda Obeyesekera Hall and elsewhere much use has been made of lacquer-work carried out by Kandyan craftsmen, who have been at work for the past five or six years. On account of expense, however, most of the architectural detail has been carried out in concrete.

Though Kandy is only four miles away, it has been necessary for the University to organize many of its own services. Water is drawn from the University estates on Hantane; gas will have to be made on the site when the laboratories come into use; electricity is taken in bulk from the hydro-electric scheme and distributed by the University as licensed supplier through three transformer stations; a separate telephone exchange is being established under University control; a University Supply Organization has been established to purchase and distribute supplies through a University shopping centre (not yet erected); an electric laundry is being established; the University owns 135 houses and expects to own another three or four hundred; and a school will have to be provided when the technical staffs of the Faculties of Science and Engineering come into residence. In short, the University Park is much like a small 'company town'.

The residential system was adopted for Ceylon after a controversy which lasted fifteen years, in which much use was made of the Sadler Report on the University of Calcutta in 1919. To the usual advantages of residential education must be added several derived from local conditions. The climate of Peradeniya is better than that of Colombo, and strenuous games can be played more easily. The great natural beauty and the flora and the fauna both of the University Park and of the Royal Botanic Gardens are of considerable educational value. The heavy concentration on examination qualifications can be diminished by residential education. The authoritarian character of parental control, though in many respects admirable, tends to curb initiative and enterprise, and makes it useful to take undergraduates away from their parents for three or four years. Some attempt can be made, too, to alter the current scale of values, which derives from a combination of caste traditions and Colonial rule.

A VERSATILE FOCUSING SYSTEM FOR VAN DE GRAAFF ACCELERATING TUBES

By P. HOWARD-FLANDERS

Medical Research Council Radiotherapeutic Research Unit, Hammersmith Hospital, London, W.12

OF the positive-ion accelerating tubes used with high-voltage generators, most have been built with focusing systems which follow the techniques developed by Tuve[1] and many others. In these, use is made of focusing lenses of the type which occur between axially spaced cylindrical electrodes at different potentials.

There is, however, an alternative system of focusing which is very suitable for use in the accelerating tubes of Van de Graaff and other high-voltage machines. This system uses the type of lens which occurs at the aperture in a diaphragm separating two regions of uniform but differing electric field-strength. It is arranged by means of a suitable resistance-potential divider that the electric field is low for a short initial section of the tube and has a uniform high value for the whole remaining length; thus forming a focusing lens at the change of gradient which can be used to bring particles admitted at one end to a focus on the target at the other.

Accelerating tubes are usually constructed with a large number of electrodes at graded potentials, as it is found that tubes of this construction stand up best to use at high voltages[2]. The electrodes are often closely spaced, so that they produce a very nearly uniform field at the tube axis. In this case, it may be assumed that the field is quite uniform, which, of course, greatly simplifies the calculation of particle trajectories, and a simple first-order non-relativistic theory has been worked out for the conditions for focusing particles on to the target.

The focal length of the aperture lens is given by the well-known formula $F = 4V/(E_2 - E_1)$ for a particle accelerated through a potential difference V on passing from a region of field E_1 to a region of field E_2, assuming that the change of gradient occurs within a range of potential small compared with V. This formula has served as the basis for calculating the results which follow. Consider an accelerating tube in which the electric field is E_1 for a distance L_1 and is E_2 for a distance L_2, followed by a field-free target extension tube of length L_3 as shown in the diagram. Let the potentials at the point of injection, at the change of gradient and at the target, be V_0, V_1 and V_2, respectively, measured relative to the potential at which the particles are at rest. Then any particles injected into the tube at a potential V_0 will be brought to a focus at the target if the following condition is fulfilled:

$$\frac{L_2}{L_1}\frac{(3p-1)(p+1)}{p^2} = \frac{4q^2(q+1)(q-3)L_2 + 3(q^2-1)^2L_3}{4q^2L_2 + (3q-1)(q+1)L_3},$$

where $p^2 = V_1/V_0$ and $q^2 = V_2/V_1$.

A real inverted image is formed of the cross-section of the beam at the point of entry into the tube, the magnification M being given by

$$M = \frac{(p+1)}{p}\frac{L_2}{L_1}\left(\frac{1}{q+1} + \frac{(3q-1)}{4q^2}\frac{L_3}{L_2}\right).$$

We can now consider the properties of an accelerating tube in which the field is graded in the way described. The appropriate potentials have been calculated for a tube in which the length of the target extension tube is comparable with the length of the accelerating tube ($L_3 = 1{\cdot}04\ L_2$), and for three cases where $L_2/L_1 = 5$, 10, or 25. The way in which V_1/V_0 must vary with change of V_2/V_0 in order to focus the particles on to the target is shown in the diagram. It will be noted that focusing cannot be maintained below a certain threshold value of V_2/V_0, usually in the range 30–100, but that above this voltage V_1/V_0 varies in an almost linear way. Straight lines can be drawn which will lie almost on top of each curve, but which depart slightly near the origin, in the manner shown by the dotted lines. V_1/V_0 can be made to vary with V_2/V_0 so as to follow the appro-

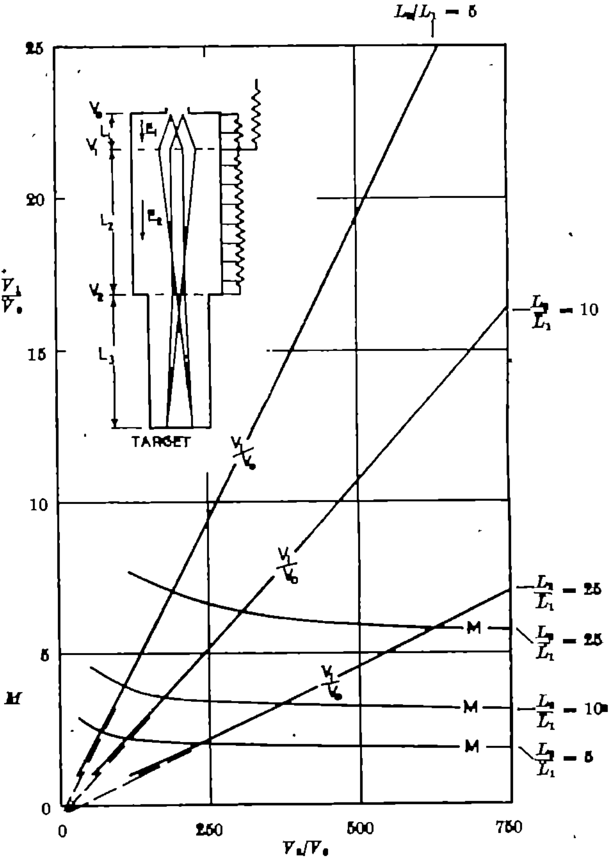

Diagram of an accelerating tube with a resistance chain to control the potential gradient. The values of V_1/V_0 required for focus, together with the corresponding magnification M, are given as a function of V_2/V_0 for an accelerating tube in which $L_3/L_2 = 1{\cdot}04$ and $L_2/L_1 = 5$, 10 or 25 priate straight line by taking V_1 from a suitable resistance chain, terminated at a potential slightly different from zero. It will then be advisable to use a second resistance in parallel with the upper part of the tube, as shown in the diagram, which will serve to grade the potential in the tube between the voltages V_2 and V_1. With a forked resistance chain of this type, V_1/V_2 can be held close to the required value over a wide range of V_2/V_1, so that the tube will be maintained in focus over a correspondingly wide range of operating voltage.

Comparing the curves for different values of L_2/L_1, it will be seen that the longer L_1 is, the wider is the voltage-range over which focusing is maintained. It will also be noted from the second set of curves, which show the magnification, that the longer L_1 is, the lower is the magnification, and hence the smaller is the target spot. The advantages of a long L_1 must, however, be set against the fact that the gradient in L_1 is lower and, for a given total length of accelerating tube, the maximum voltage which the tube will withstand is likely to be reduced by increasing L_1 at the expense of L_2. The choice of the best length L_1 is therefore a compromise, and the best value will depend upon the particular purpose for which the system is to be used.

We can now consider how a machine will behave which uses this focusing system. If particles are injected from an ion source working at, say, 4 kV., and if L_2/L_1 is 10, we can expect the system to be in focus when working at any potential above about 300 kV. There are other useful features of a focusing system of this kind. It will operate with large-diameter electrodes, so that it can be made to accept and focus particles injected at larger angles to the axis than is the case with the focusing system first mentioned. Further, as the current drain to large-diameter electrodes is small, it is not necessary to use any high-voltage focusing power-pack, all potentials being drawn from the resistance-potential divider. This simplifies the construction of the high-voltage terminal and the operation of the machine. It also facilitates the use of a single tube, operated at the appropriate polarity, for accelerating electrons or positive ions.

This focusing system has been tested in a preliminary way on the 2-MeV. pressurized Van de Graaff generator at the Radiotherapeutic Research Unit of the Medical Research Council and is used for accelerating positive ions or electrons as required. Ions are injected into the tube at a potential of about 200 volts into a uniform field E_1 which extends about one-tenth of the distance along the tube to the region where the field increases to the higher value. The full internal diameter of the electrodes in the accelerating tube is maintained without any diaphragm or constriction, so that the change of gradient is spread out axially to some degree. However, good focusing has been obtained over a wide range of voltage and current for both electrons and positive ions. The resistance values in the potential divider are set in advance to the theoretical value and there is no provision for adjustment in use. The resistance-potential divider has proved adequate for controlling the gradient for ion currents three or four times larger than drain through the resistances, indicating that the current to the large-diameter electrodes is very small. The observed magnification has been found to be in rough agreement with that predicted by the theory. The introduction of this focusing system has greatly improved the focus of the beam and has made possible some increase in the maximum currents obtained with this machine. The accelerating tube has been used to carry 350 μamp. of mixed positive ions at 2 MeV. continuously and more than 500 μamp. for short periods.

I am indebted to Mr. T. Wilson, whose formulation of the condition $L_1 = 2V/(E_2 - E_1)$ for the collimation to parallel of a divergent beam of particles injected with small velocities constituted one of the early steps in the development of the general formulæ presented above. [June 20.

ESTIMATION OF THE 'BOUND FORM' OF NICOTINIC ACID

By Dr. K. K. REDDI

Dunn Nutritional Laboratory, University of Cambridge
and Medical Research Council

IT is now well established that in some cereals the nicotinic acid is present to a large extent in a bound form, which is alkali labile[1–8]. Krehl and Strong[8] called this form the precursor of nicotinic acid. The assay methods employed for the estimation of the bound form are essentially microbiological. These microbiological assays do not give a correct estimate of the amount of the bound form, since the various organisms employed for these assays seem to utilize to a certain extent the intact precursor as a source of nicotinic acid. Thus, for example, *Lactobacillus arabinosus* seems to utilize the precursor up to about 45 per cent[9] or to 80 per cent[8], while *Lactobacillus casei* could utilize it to the extent of 10–20 per cent[10]. These considerations must obviously be taken into account in interpreting the results of microbiological assays.

The method I have employed is based on earlier observations that the 'bound form' does not move on paper chromatograms, developed in *n*-butanol – water solvent system or in 60 per cent *n*-propanol, but remains at the origin[11]. Its position can be located by its bluish-white fluorescence under ultra-violet light and by its orange colour when treated with cyanogen bromide and *p*-aminobenzoic acid[11]. In the case of materials containing the coenzymes, it is better to develop the chromatograms in 60 per cent *n*-propanol, since in this solvent system coenzymes I and II have the R_F values 0·26 and 0·15, respectively[11]. The interference with coenzymes that survive the following extraction procedure is eliminated. Thus it is easy to separate quantitatively the bound form from other nicotinyl compounds by developing the chromatograms in a suitable solvent system.

The procedure for the quantitative estimation described below consists in: (1) extraction with acidic methanol, (2) separation of the bound form on the chromatograms, (3) elution with *N* sodium hydroxide and estimation as free nicotinic acid. The values for the amount of the 'bound form' in the samples analysed were expressed in terms of free nicotinic acid.

(1) *Extraction.* 2–5 gm. of the material was extracted by refluxing on a water-bath with 20 ml. acidic methanol (80 ml. methanol + 20 ml. 0·5 *N* hydrochloric acid) for 1 hr., and after cooling the supernatant liquid was decanted. The residue was extracted with 20 ml. acidic methanol in the same

way for 1 hr. and the supernatant liquid was decanted. The residue was again washed twice with 10 ml. acidic methanol each time and the washings were added to the supernatant liquid. The combined supernatant fluids were kept in the ice chest for 30 min. and the bulky precipitate that separated was centrifuged. The clear centrifugate was decanted off, and the residue in the centrifuge tube was washed with 10 ml. acidic methanol each time and centrifuged. The combined centrifugates were evaporated to dryness at 55–60° C. under reduced pressure. The residue was extracted with 4 ml. of distilled water and centrifuged. The clear 'aqueous extract' contained the whole amount of the 'bound form' (see table).

NICOTINIC ACID CONTENT (μgm./gm.) AS DETERMINED BY DIFFERENT PROCEDURES

Material	Total nicotinic acid (*N* NaOH digestion)	'Aqueous extract' from acidic methanol extraction (*N* NaOH digestion)	Present procedure (*N* NaOH elution from paper strips)
Wheat bran	245	253	249
Rice bran	287	307	291
Groundnut (defatted with ether)	276	218	nil
'Gluten Feed 6' (maize bran)	56*	50	nil

* 5 gm. 'Gluten Feed' was extracted with 50 ml. 0·1 *N* hydrochloric acid on a water-bath. An aliquot was digested with *N* sodium hydroxide for 30 min. on a water-bath.

(2) *Separation of the bound form by paper chromatography*. 0·01-ml. spots of the 'aqueous extract' were placed on Whatman No. 1 filter paper and descending chromatograms were run overnight employing *n*-butanol – water as the solvent system. The chromatograms were dried at room temperature. The spots at the origin of the chromatograms were marked with pencil under ultra-violet light and the strips were cut out.

(3) *Elution with N sodium hydroxide*. The filter paper strips (5–10 spots) containing the 'bound form' were transferred to a beaker and 20 ml. *N* sodium hydroxide added. They were worked into fine pulp with a glass rod and digested on a water-bath for 30 min. with frequent stirring. The contents were cooled and centrifuged. The residue was extracted twice with 10 ml. *N* sodium hydroxide each time and centrifuged. The combined centrifugates were adjusted to *p*H 6·8 and the volume was made up to 45 ml.

The estimation of nicotinic acid was done by means of the colour reaction with *p*-aminoacetophenone and cyanogen bromide[12], following the revised procedure of Wang and Kodicek[13].

Nicotinic acid in the 'aqueous extract'. An aliquot was digested with 20 ml. *N* sodium hydroxide for 1 hr. on a water-bath and the nicotinic acid was estimated.

Total nicotinic acid. 1–2 gm. of the material was digested with 50 ml. *N* sodium hydroxide for 1 hr. on a water-bath and the nicotinic acid was estimated.

From the results (see table) it appears that in wheat and rice bran the entire nicotinic acid is present in a bound form, whereas in groundnut about 21 per cent of the total nicotinic acid is present in a form which is not extractable with acidic methanol. The higher values obtained by alkali digestion by Sohonie and Misra[14] in the case of groundnut digested with alkali were attributed either to the presence of a bound form or to some non-specific substance. Since the nicotinic acid extractable by acidic methanol was not recovered at the origin of the chromatograms (see table, col. 3), it appears that no 'bound' nicotinic acid of the type found in wheat or rice bran was present.

In a preparation of 'Gluten Feed' (a proprietary maize-bran product) there was no bound form and the entire nicotinic acid was extracted with acidic methanol. The chromatograms of the aqueous extract adjusted to *p*H 5·2 showed the presence of free nicotinic acid, and added nicotinic acid occupied the same position on the chromatogram as that present in the aqueous extract. It is quite likely that in 'Gluten Feed' the nicotinic acid is present in a free form. The pellagragenic nature of the 'Gluten Feed' could be attributed to the presence of a factor or factors which somehow prevent the utilization of the nicotinic acid by the animal system. These factors are most probably alkali-labile, since the digestion with alkali converts pellagragenic material into a pellagra-preventive foodstuff[15].

I wish to thank the Flour Millers' Association for the supply of wheat and rice bran. [June 27.

CELL WALL OF *MICROCOCCUS LYSODEIKTICUS* AS THE SUBSTRATE OF LYSOZYME

By M. R. J. SALTON

(Beit Memorial Research Fellow)

Dept. of Colloid Science, University of Cambridge

THE rapid lysis of intact cells of *Micrococcus lysodeikticus* by egg-white lysozyme has left little doubt that this enzyme radically alters some structure involved in the maintenance of the cell's morphological integrity[1]. Although Boasson[2] claimed that the cell wall of *Micrococcus lysodeikticus* was not destroyed by lysozyme but merely rendered more permeable to cellular contents, recent work[3] with the electron microscope has shown degradation and final destruction of the cell wall by lysozyme.

In view of the foregoing evidence, it seemed worth while studying the action of lysozyme on the bacterial cell wall. *Micrococcus lysodeikticus* and *Sarcina lutea* have been found to be refractory to sonic disintegration[4]; but the procedure reported by Salton and Horne[5] has been successfully used in preparing the cell walls of these organisms.

Cell walls prepared from 24-hr. cultures of *Micrococcus lysodeikticus* gave a stable, milky-white,

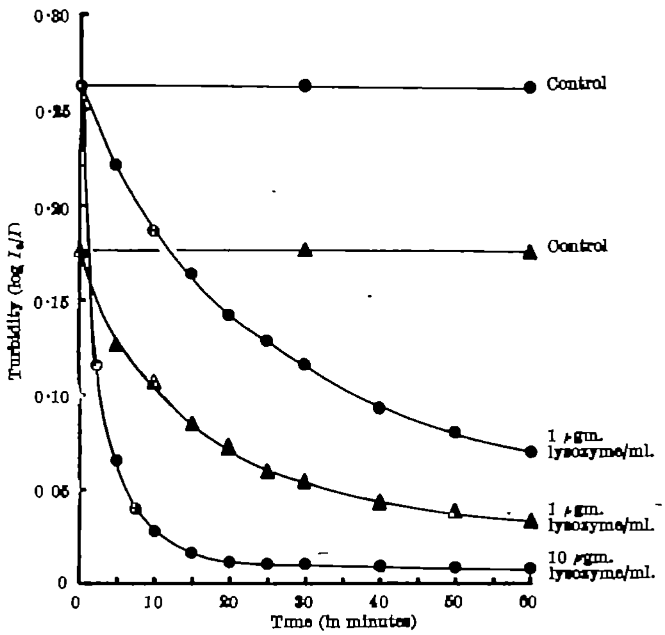

Fig. 1. Progress of dissolution of cell walls of *Micrococcus lysodeikticus* by lysozyme at 37° C., in 0·1 *M* phosphate buffer at *p*H 6·2.
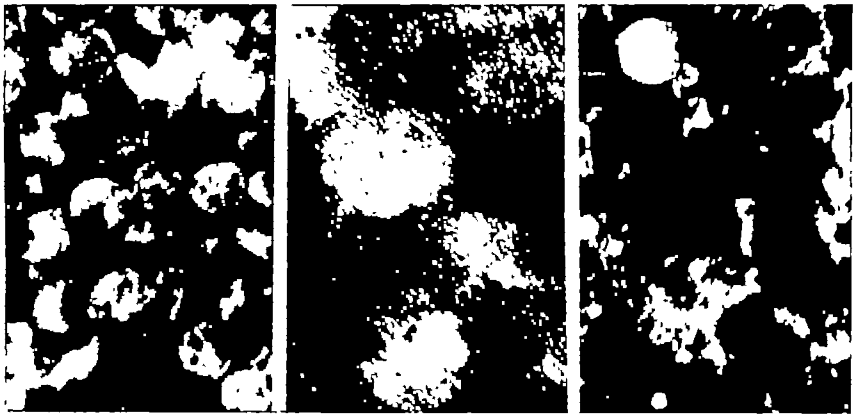
●——●, 150 μgm. dry-weight cell walls/ml.
▲——▲, 100 μgm. dry-weight cell walls/ml.



(*a*) × 5,000 (*b*) × 5,000 (*c*) × 6,500

Fig. 2. (*a*) Untreated suspension of cell walls of *Micrococcus lysodeikticus*. Shadowed at 30° with gold–palladium alloy (60/40 per cent)

(*b*) Cell-wall suspension taken at the point of half-lysis (2½ min. exposure to 10 μgm. lysozyme/ml. at 37° C.). Specimen shadowed at 12°–15° with gold–palladium alloy

(*c*) The concentrated residue remaining after maximum clearing (60 min., 10 μgm. lysozyme/ml. at 37° C.) of the cell-wall suspension. Shadowed as for (*a*)

opalescent suspension. They were suspended in 0·1 *M* phosphate buffer at *p*H 6·2, and the rate of dissolution of the cell walls by lysozyme (Armour Laboratory crystalline, egg-white lysozyme) at 37° C. was followed by measuring the turbidity changes in a Hilger 'Spekker', using yellow-green filters. Lysozyme was dissolved and diluted in 0·9 per cent saline and added to cell-wall suspensions, the dry weights of which were determined by drying aliquots to constant weight at 105° C. The progress of 'lysis' of the cell walls was followed by pipetting 2-ml. aliquots into 0·25-cm. (internal width) cells and reading immediately in the 'Spekker'. Fig. 1 shows the results. A set of curves identical with those in Fig. 1 was obtained when cell walls were suspended in 0·9 per cent saline instead of phosphate buffer.

The rate of dissolution of the cell walls of *Micrococcus lysodeikticus* by lysozyme did not differ significantly over the *p*H range 5·7–7·0 (0·1 *M* phosphate buffers).

In order to determine the nature of the changes lysozyme had effected in the cell-wall structures as seen in the electron microscope, suspensions of the walls of *Micrococcus lysodeikticus* (150 μgm. dry-weight/ml.) were taken at the point of 'half-lysis' (approximately 2½ min. with 10 μgm. lysozyme/ml.) and after maximum clearing (60 min., 10 μgm. lysozyme/ml.). Suspensions were diluted with a large volume of ice-cold distilled water to reduce enzyme action and immediately centrifuged at 10,000 r.p.m. for 20 min. The deposits were re-suspended in distilled water, suitably diluted, and small drops placed on electron-microscope grids and examined in the electron microscope after shadowing specimens with gold–palladium alloy (60/40 per cent). Figs. 2 *a*, *b* and *c* show, respectively, the appearance of untreated cell walls, the half-lysed suspension and the residue (this deposit was re-suspended in two drops of distilled water and therefore represents a considerable degree of concentration of residual material). Partial depolymerization of cell walls, as shown in Fig. 2*b*, is characterized by an apparent reduction in the thickness and rigidity of the wall. The residual material, which accounts for 3–4 per cent of the original turbidity of the cell-wall suspension, consists of cell-wall fragments, a few cell walls which have apparently escaped dissolution and some electron-dense, cytoplasmic debris which probably contaminated the original preparation. These results suggest that there is no evidence for the existence of a lysozyme-resistant framework forming part of the cell wall of this organism, and that lysozyme effects a depolymerization of the whole cell-wall structure, rather than a degradation of a specific part or layer of the wall.

It seems reasonable to conclude that the cell wall of *Micrococcus lysodeikticus* is the insoluble, highly polymerized, mucopolysaccharide substrate of lysozyme. Further investigation of the constitution of the cell wall of *Micrococcus lysodeikticus* and its degradation by lysozyme is proceeding.

I wish to thank Mr. R. W. Horne, of the Cavendish Laboratory, for taking the electron micrographs.

Action of Salivary α-Amylase on Amylopectin and Glycogen

Roberts and Whelan[1] have shown that the action of salivary α-amylase on amylose is consistent with the view that the enzyme can hydrolyse any except the terminal α-1 : 4-linkages. This leads to the formation of maltose and maltotriose. Similar studies using the linear maltodextrins[2] have confirmed this hypothesis[3]. We now wish to make a preliminary report of the action of this enzyme on glycogen and amylopectin.

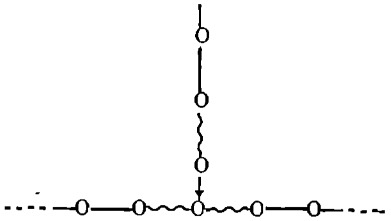

Fig. 1. α-1 : 4-Linkages resistant to α-amylase action
O, Glucose unit; —, α-1 : 4-link; ∼∼, unhydrolysable α-1 : 4-link; →, α-1 : 6-link

Rabbit liver glycogen (from pregnant does) was exhaustively treated with enzyme purified by the method of Meyer *et al.*[4] and the products were fractionated on a charcoal–'Celite' column[4,5]. Maltose ($4 \cdot 57 \times 10^{-6}$ moles), maltotriose ($2 \cdot 25 \times 10^{-6}$ moles) and dextrins containing α-1 : 6-branch linkages were obtained, but a tetrasaccharide fraction was absent. It was confirmed by paper chromatography that the branched dextrin of lowest molecular weight was a pentasaccharide. The branched dextrins were treated with *R*-enzyme, which hydrolyses the α-1 : 6-linkages[6,7], and the products were again fractionated on charcoal. The following substances were obtained (amounts in 10^{-6} moles): maltose (1·73), maltotriose (1·73), maltotetraose (1·32), maltopentaose (0·26) and dextrins of higher molecular weight (0·25). These observations are consistent with the following hypothesis of salivary α-amylase action. In Fig. 1 is shown the portion of a ramified polysaccharide in the vicinity of a branch linkage. and it is postulated that each of the three α-1 : 4-links adjacent to the branch link is, in virtue of its position, resistant to hydrolysis by α-amylase.

In the random action of α-amylase, maltose and maltotriose will be liberated from the linear portions of the molecule. Action in the vicinity of the branch linkages must give rise to a mixture of eight branched dextrins if the hypothesis is correct (Fig. 2). It will be seen in the first place that the smallest of these dextrins is a pentasaccharide. This agrees with the observed absence from the α-dextrins of a tetrasaccharide. Secondly, hydrolysis of the α - 1 : 6-linkages by *R*-enzyme will give rise to a mixture of maltose, malto-triose, -tetraose and -pentaose, in agreement with the experimental results. Maltodextrins of greater chain-length than maltopentaose were also liberated by the action of *R*-enzyme (see above). This observation is not, however, at variance with the hypothesis, since it is to be expected that structures of the type shown in Fig. 3 will also be present in the branched polysaccharides. Both (*a*) and (*b*) will give rise to α-dextrins containing two branch-linkages per molecule, whereas the types illustrated in Fig. 2 contain only one link. The hypothesis of resistant 1 : 4-linkages requires that structures 3*a* and 3*b* should each give rise to twelve possible α-dextrins. Three of those derived from the first type (Fig. 3*a*) would, after *R*-enzyme action, produce maltohexaose, which would also result from the debranching of six of the α-dextrins from structure 3*b*; maltoheptaose would be produced from three of the latter α-dextrins. The measured average chain-length of the mixture of higher dextrins produced by *R*-enzyme action was 6·1, and paper chromatograms confirmed that it consisted of hexa- and hepta-saccharides. It should be noted that, if these inferences can be substantiated, the production of 6- and 7-unit maltodextrins constitutes a proof of *multiple* branching in glycogen. Peat, Whelan and Thomas[8] have already reported evidence of such branching in waxy maize starch.

The information given above may be used to determine the average length of the repeating chains in the branched polysaccharides. A knowledge is required of the difference in the number of molecules in the α-dextrin sample before and after *R*-enzyme action. Thus, in the case of glycogen, calculation gives a value of 12·5 as the number of glucose units in a repeating chain, which may be compared with the value of 13·6 determined in this laboratory by periodate oxidation of the same glycogen.

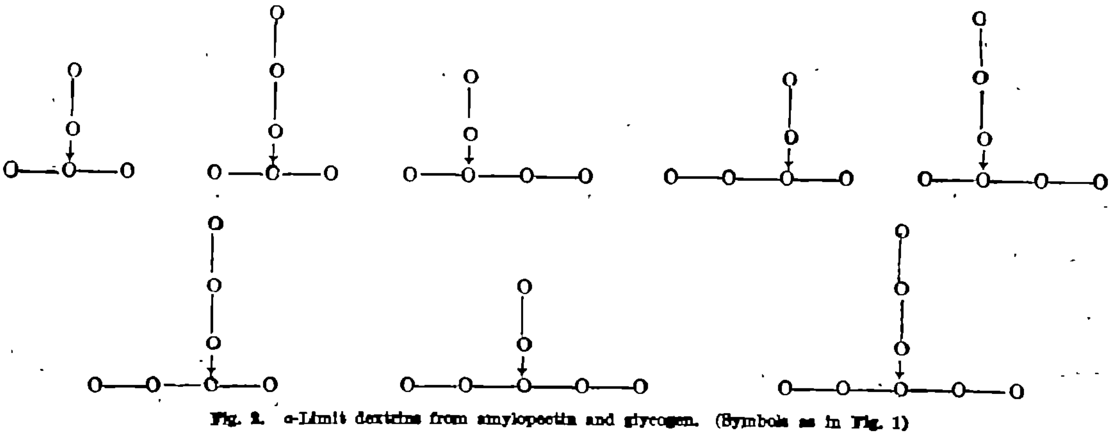

Fig. 2. α-Limit dextrins from amylopectin and glycogen. (Symbols as in Fig. 1)

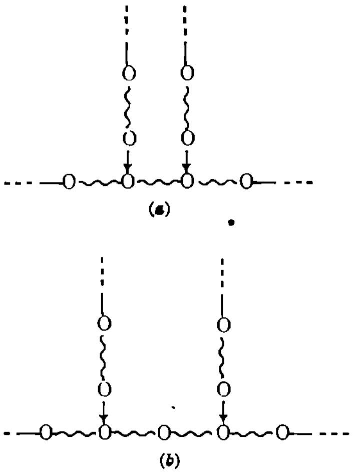

Fig. 3. Structures giving rise to doubly branched α-dextrins (Symbols as in Fig. 1)

Mention must be made of the presence of fructose in these polysaccharides. As reported recently[9], fructose, in the form of maltulose, has been isolated from rabbit liver glycogen after α-amylase action. In addition, fructose has now been detected in the maltotriose and all other α-dextrin fractions arising from this glycogen. This is also true of waxy maize starch[10]. These findings do not, however, influence the above argument with respect to α-amylase action.

We are indebted to Prof. S. Peat for his continued interest in this work, and to Prof. F. Rogers Brambell for the supply of the rabbit livers.

Cysteic Acid Transaminase

It has previously been reported by Cohen[1] that enzyme preparations catalysing the reactions:

(1) Alanine + α-ketoglutarate $\rightleftharpoons$ glutamate + pyruvate;

(2) Aspartate + α-ketoglutarate $\rightleftharpoons$ glutamate + oxalo acetate;

are also capable of catalysing:

(3) Cysteic acid + α-ketoglutarate $\rightleftharpoons$ glutamate + sulphopyruvate.

(In a succeeding paper it will be shown that reaction (3) is reversible, which has hitherto not been proved.)

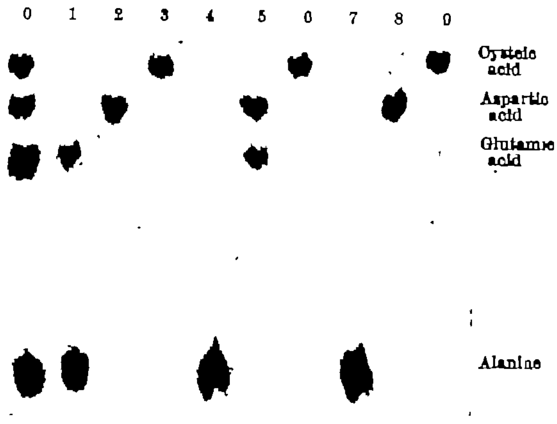
Furthermore, Green *et al.*[2] have shown that (1) and (2) are catalysed by means of two different enzymes, alanine and aspartic acid transaminase.

In experiments reported here, strong evidence is given for the existence of a special enzyme, cysteic acid transaminase, which catalyses reaction (3).

The enzyme is prepared by extraction of acetone-dried ox hearts with water. The liquid is pressed through a linen cloth, and the active material is precipitated with ammonium sulphate at 80 per cent saturation. The precipitate is filtered off and suspended in water and dialysed in a 'Cellophane' tube for 24 hr. The undissolved residue is centrifuged off and discarded. Then the solution is heated for five minutes at 60° C. The heat-coagulated protein is centrifuged off, and the clear supernatant liquid which contains the whole activity is subjected to fractionation with ammonium sulphate. By stepwise increase of the ammonium sulphate concentration, three fractions, *T*(0–50), *T*(50–65), *T*(65–80), are obtained; the numbers in brackets denote the concentration limits, expressed as percentage of saturation, between which the fractions are precipitated. Each of the fractions is examined with regard to its ability to catalyse the three above-mentioned reactions.

The technique adopted in this investigation consisted in incubating the amino-acids together with α-ketoglutaric acid in the presence of the enzyme fractions at 30° C. and *p*H 7·5. After a suitable lapse of time (10 min. in the present experiments), 0·1 ml. of 75 per cent phenol-water mixture is added for each 1 ml. of reaction mixture in order to arrest the reaction. The time of incubation is adjusted so that the relationship between time and the degree of reaction can be considered as linear with good approximation for all of the reactions.

The glutamic acid formed from the ketoglutarate by transamination was separated on filter paper by unidimensional chromatography using 75 per cent phenol as the solvent. In the photograph the qualitative results of a typical experiment are shown. Experimental conditions: 0·5 ml. of 0·1 *M* ketoglutaric acid and 0·5 ml. 0·1 *M* amino-acid solution are incubated for 10 min. with 0·5 ml. enzyme solution, *p*H 7·5, phosphate 1/15 molar, temperature 30° C.



Phenol/water chromatogram showing the formation of glutamic acid from α-ketoglutarate and L-alanine (1), L-aspartic acid (2), L-cysteic acid (3) in the presence of enzyme fraction *T*(0–50); α-ketoglutarate and L-alanine (4), L-aspartic acid (5), L-cysteic acid (6) in the presence of *T*(50–65) and from α-ketoglutaric acid and L-alanine (7), aspartic acid (8) and L-cysteic acid (9) in the presence of fraction *T*(65–80). For comparison, a mixture of cysteic acid, aspartic acid, glutamic acid and alanine is run on the same paper (0)

The reaction is arrested by adding 0·15 ml. 75 per cent phenol – water mixture. For analysis 4 µl. of each mixture is used. The chromatogram is developed with 75 per cent phenol – water mixture on Whatman No. 1 paper. After drying for 1 hr. in an oven at 80° C., the paper is sprayed with 0·1 per cent ninhydrin in butanol. After drying in an air current at room temperature for 5 hr., the chromatogram is photographed.

It can be seen from the chromatogram that (1) is catalysed by *T*(0–50) but not by *T*(50–65), as opposed to (3) which is catalysed by *T*(50–65) as well as by *T*(65–80). Hence alanine transaminase is not identical with the enzyme which catalyses (3). Furthermore, judging from the intensities of the glutamic acid spots, *T*(50–65) is more effective for (2) than for reaction (3), whereas the opposite holds for *T*(65–80). These results are consistent with quantitative results which will be published in due course.

Thus one can conclude that an enzyme, cysteic acid transaminase, exists, which is different from alanine transaminase and aspartic acid transaminase.

Fœtal Fructose in Various Mammals

FRUCTOSE has been reported to occur in the fœtal fluids of a variety of animals, and it has been implied that this sugar is present generally in mammalian fœtuses[1]. However, the earlier claim that fructose occurs in the human fœtus[2] has been refuted[3]. The problem has been re-investigated here during a comparative study of carbohydrate metabolism and related disease problems in the new-born.

Mixed blood samples were obtained mainly from the umbilical cord, or, in the case of the carnivores, from throat blood after decapitation, at birth. Sheep and rodent samples were from the cord and throat blood respectively of near-term fœtuses. After collection over potassium oxalate, the blood was deproteinized at once with sodium hydroxide and zinc sulphate, except for foal blood, when barium hydroxide and zinc sulphate were used. In a proportion of foal samples, difficulties resulting from inconvenient foaling times necessitated sampling over sodium fluoride to check glycolysis during several hours delay before protein precipitation.

Fructose was measured colorimetrically by a modification of the Seliwanoff reaction, using glycerol as solvent and copper as catalyst, in a boiling water-bath. The method developed, on the average, 1·5 mgm. of fructose colour from 150 mgm. of glucose. Standard fructose solutions were included with each boiling, and blanks of reagents plus distilled water were subjected to identical procedures. Total sugar was measured by a modification of the method of Somogyi[4] and correction made for the unequal reducing powers of fructose and glucose. Both methods, as employed here, had a standard deviation of 1 mgm. per cent on 20 similar samples.

The findings are shown in the accompanying table. The classification into orders, although not strictly exact, aids description in the text.

Order	Animal	No. of pregnancies	No. of young	Blood fructose
Ungulata	Horse	20	20	Positive in all
	Pig	12	60	Positive in all
	Ox	1	1	Positive
	Sheep	8	11	Positive in all
	Goat	1	1	Positive
Carnivora	Dog	1	4	Negative in all
	Cat	2	5	Negative in all
	Ferret	1	3	Negative in all
Rodentia	Guinea pig	5	9	Negative in all
	Rabbit	2	11	Negative in all
	Rat	1	Pooled blood from 8	Negative

In addition, fructose was not found in the amniotic fluid of the hen's egg after eight, nine and eleven days incubation.

Actual fructose-levels in blood are not given for the ungulates, as these must be related to parturition and other factors; but they were of the order as those previously reported for the sheep and, with few exceptions, fell between 25 and 130 mgm. per cent.

Slight fructose values which are obtained in the non-ungulate group are difficult to interpret, because the interfering colour from glucose and other chromogens is slightly variable as, also, is the blank colour. From the fact that this colour never exceeded an equivalent as fructose of 3 mgm. per cent above that calculated to be present from glucose, and was frequently much less, fructose has been assumed to be absent, or present only in such trace amounts as might exist in adult blood.

These results suggest that the presence of substantial quantities of fructose in the fœtal blood of land mammals, at or near term, is peculiar to ungulates.

I have had much kind assistance in this work, which will be acknowledged when a more detailed account is presented.

Activation of the Fluorescence of Chlorophyll Solutions

CHLOROPHYLL dissolved in pure dry hydrocarbons is (practically) non-fluorescent[1-3]. The addition of traces of water, alcohols or amines to solutions of chlorophyll restores their fluorescent intensity to that observed in solvents such as methanol, ether, etc. It was demonstrated by Livingston, Watson and McArdle[1] that this increase in the fluorescent yield is the result of the formation of an addition compound between a molecule of chlorophyll and one of the 'activator'. These authors postulated that the addition compound was formed by the establishment of hydrogen bonds between labile hydrogens of the activator and the keto oxygens of ring V[4] of the chlorophyll molecule. Afterwards, Evstigneev, Gavriola and Krasnovskii[5] presented evidence supporting the view that the activator adds to the central magnesium atom rather than to ring V. They claimed that the fluorescence of pheophytin is as intense in dry as it is in wet toluene, but that the fluorescence of toluene solutions of the magnesium complex of phthalocyanine is increased by the addition of water.

These results[3] with pheophytin solutions have been fully confirmed in our laboratory. However, the conclusions in regard to the phthalocyanines appear to be in error. A 'solution', prepared by mixing dry toluene with an ethereal solution of the magnesium complex of phthalocyanine and then pumping off the ether, is colloidal in nature. The optical density of such a preparation decreases rapidly with time, and if allowed to stand for a few days the blue pigment settles to the bottom, leaving a clear supernatant liquid. In spite of their misinterpretation of the experiments on phthalocyanine preparations, their contention that the activator molecule becomes attached to the magnesium atom appears to be correct.

The equilibrium constant, K, for the formation of the addition compound can be determined from measurements of either the absorption coefficients or the intensity of fluorescence of the solutions. Using quinoline as the activator and chlorophyll *a* as the pigment, identical values for K, of $1 \cdot 33 \times 10^4$ moles/litre, were obtained from measurements of the fluorescent intensity and of the absorption coefficients. From measurements of the changes in the absorption coefficients, it has been shown that magnesium, zinc- or calcium-complexed mesoporphyrin dimethyl ester, magnesium-complexed tetraphenyl chlorin[5], and zinc- or calcium-substituted chlorophyll form addition compounds with alcohols and organic bases. The stability constants of some of these compounds are listed in the accompanying table.

VALUES OF THE STABILITY CONSTANTS OF THE PIGMENT-SOLVENT ADDITION COMPOUNDS

Activator	Pigment			
	Mg-Porph.	Zn-Porph.	Mg-Chph.	Zn-Chph.
Aniline	41		46	
Benzyl alcohol	1,120		2,900	
Quinoline	8,300	1,800	13,300	15,200
Heptylamine	110,000		160,000	

Since the uncomplexed (that is, metal-free) forms of these pigments do not show any change in absorption spectra or in fluorescent intensity when alcohols, etc., are added to their solutions in dry hydrocarbons, presumably they do not form addition compounds of this type.

The evidence in support of the hypothesis that the 'activator' molecules add to the metal ion of the pigment may be summarized as follows. (1) Only the metal-complexed pigments form such compounds; the corresponding compounds containing imide hydrogens do not react in this way. (2) The stabilities of the addition compounds of chlorophylls, chlorins and porphyrins are all of the same order of magnitude. (3) All the known activators are generalized bases (that is, nucleophilic reagents), and this seems to be the only characteristic which they have in common. (4) Allomerized as well as native chlorophyll[1] shows the effect, although presumably the former molecule cannot undergo a keto-enol tautomerism on ring V [4].

It is noteworthy that, of the pigments investigated, only the magnesium chlorophylls exhibit a marked change in fluorescent yield accompanying the formation of the addition compound. At room temperature the fluorescent yields of the addition compounds of native chlorophylls *a* and *b* are at least twenty-five-fold greater than the yields of the same pigments in base-free solvents. Under similar conditions, zinc-chlorophyll *a* shows about a 20 per cent increase in fluorescent yield. There is no detectable change in the fluorescent yields of the metal-complexed porphyrin or tetraphenyl chlorin.

In dry benzene, the Soret band of the absorption spectrum of mesoporphyrin appears as two maxima of equal height, situated at 4060 A. and 4160 A. The addition compounds of this pigment with methanol, benzyl alcohol, aniline, heptylamine and quinoline exhibit the usual single narrow absorption peaks, at 4100, 4110, 4120, 4130 and 4130, respectively. None of the other pigments exhibits such splitting of their principal absorption bands.

The detailed results upon which this note is based will be published elsewhere. The experimental work was made possible by the support of the U.S. Office of Naval Research (Project 059, 028, Contract N6, ori 212, T.O. I).

Histochemical Differentiation of *cis-trans* 1-2 Glycols

SINCE McManus[1] introduced his periodic acid technique for histochemical localization of the 1-2 glycol linkage, the field has been well investigated. Other techniques have been devised, utilizing both periodic acid[2] and lead tetraacetate[3-5], to split the carbon–carbon single bond of the glycol to produce leucofuchsin-demonstrable aldehyde radicals. In all these studies, however, little attention was paid to the linkage itself but rather to the parent compound. The present investigation was undertaken to study the *cis-trans* isomerism of the 1-2 glycol linkage during this oxidative process.

The periodic acid – Schiff technique, as now generally accepted[6], consists of oxidation of tissue sections in aqueous 0·5 per cent periodic acid for 5 min. at room temperature, followed by 15 min. staining in leucofuchsin. The stained sections are then processed in the routine Feulgen manner. Glycol cleavage is considered complete in 5 min., and further oxidation is unnecessary.

Criegee and others[7,8] have shown that there is a definite sequence of reaction with both periodic acid and lead tetraacetate in splitting 1-2 glycols. Initially, the *cis* isomers are attacked in preference to the less accessible *trans* forms. Then, as the reaction continues, the *trans* isomers are attacked to complete the cleavage of all the glycol forms.

To study this aspect of glycol oxidation histochemically, two series of experiments were prepared, one utilizing gelatin blocks and the other using tissue sections. The gelatin blocks were prepared after the manner of Lessler[9] and were impregnated individually with isomers of cyclohexane glycols. The tissue sections were routinely prepared by the paraffin method from formalin-fixed blocks of rabbit, rat and human intestine. These preparations were simultaneously submitted to timed oxidations in 0·5 per cent periodic acid. Following oxidation, they were processed by the McManus method. The amount of violet coloration produced by the leucofuchsin was then studied as to intensity, and, in the case of the tissue sections, location.

Cleavage of the *cis* cyclohexane isomers in the gelatin blocks was apparent after 10 sec. oxidation, and the reaction appeared complete after 1 min. The *trans* isomers, reacting more slowly, did not show positive coloration until after 30 sec. oxidation and continued to develop colour until 2 min. after oxidation.

Tissue sections appeared to give a 'diphasic' colour development which could be correlated with the gelatin block findings. After 1 min. of oxidation, leucofuchsin-positive material could be detected on the periphery of the mucin content of goblet cells and in the cuticular margin of the columnar cells. The colour intensified with further oxidation, reaching a maximum in about 3 min. After 2 min. of oxidation, the centre of the mucin mass of the goblet cells also began to show coloration, which increased in intensity with further oxidation, reaching its maximum after 5 min. There also appeared to be a definite variation in the cleavage-rate in the goblet cells at the base of the villi and those toward the lumen. The mucin of the deeper cells gave a positive leucofuchsin reaction much sooner than that of the outer cells, in many cases showing almost complete coloration after only 3 min. of oxidation. Conversely, it often took 6–7 min. of oxidation to demonstrate completely the mucin of the outer goblet cells.

This differential glycol cleavage is more noticeable when uncatalysed lead tetraacetate[4] is used as the oxidizing reagent. The oxidation proceeds more slowly and is not complete until after 30 min. The *cis* isomer cleavage is not completed for almost 15 min., while the *trans* isomers are not initially attacked until after at least 10 min., of oxidation.

These experiments seem to indicate that it is at least empirically possible to differentiate histochemically the *cis* isomers of the 1-2 glycol linkage from the *trans* forms by the rate of cleavage during periodic acid oxidation. Those glycols which can be demonstrated after 2 min. of periodic acid oxidation would appear to be of the *cis* type, while those appearing after that time are probably mainly of the *trans* form. If this assumption is true, it will be a great help in accurately determining the exact nature of the compounds containing 1-2 glycol linkages in various tissue components.

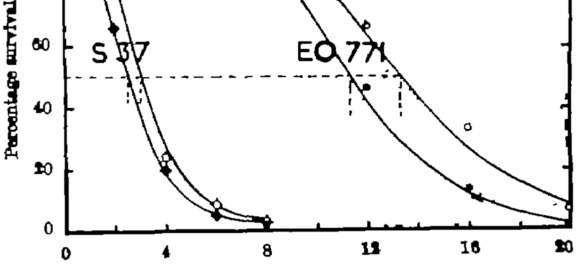
Relative Biological Effectiveness of Betatron and Conventional X-Radiation on the Regression of Mouse Tumours

THE development of more-powerful sources of X-radiation has made possible the investigation of the biological effectiveness of a variety of ionizing radiations. *In vitro* experiments have suggested that radiations of higher specific ionization have a greater lethal effect on mouse tumours[1]. We have compared the relative biological effectiveness, on two types of mouse tumours, of 200-kV. radiations from a conventional X-ray machine with 23·5-MeV. radiations from the University of Saskatchewan betatron.

The tumours used were mammary gland adenocarcinoma *EO*771 and sarcoma 37 and were carried in *C*57 × *C*3*H* hybrid mice. The transplants were made into the right axillary region of healthy hosts by the trocar method. For radiation, the mice were placed in lead containers with the tumour projecting, and irradiation was limited to the tumour. The sarcoma 37 was radiosensitive and the radiation was given in a single dose. Adenocarcinoma *EO*771 was relatively insensitive, and to attain a sufficiently high dosage the dose was fractionated, 4,000 r. being given weekly until the full dosage was reached. Tumours had attained a volume of 100 mm.^{3} when irradiated. Lethal regression was judged both by immediate decrease in size and finally by the disappearance of the tumour within three weeks of radiation. The results are shown in the accompanying graph.

Using the method of Bliss[2], the sigmoid survival curves were converted to straight lines and the mean lethal doses were determined. These were 13,500 ± 700 r., and 11,400 ± 700 r. for betatron and 200-kV. radiation respectively with adenocarcinoma *EO*771; 3,100 ± 200 r., and 2,500 ± 200 r. for betatron and 200-kV. radiation with sarcoma 37. This gave values for the ratio of effectiveness of the two radiations of 0·87 ± 0·05 with tumour *EO*771, 0·81 ± 0·08 for *S*37. It is of interest that the ratios obtained agreed closely with that found with these same tumours, at lower dosage-levels of these radiations, as judged by decrease in volume of the tumour[3], and were of the same order as the ratio obtained for the relative lethal effect on yeast[4]. In contrast, the relative effectiveness of the betatron radiation in causing leucopenia in mice[5] was 0·6, which suggested that the effective dose received by the mouse tumour per unit tolerance dose was higher for the betatron radiation than for the conventional 200-kV. X-radiation. The mean specific ionization for betatron radiation is 6·2 com-



pared to 55 for 200-kV. radiation[6], or a ten-fold difference in specific ionization. Sugiura[1], comparing gamma radiation with 200-kV. radiation, obtained a ratio of biological effectiveness of 0·67 for a sevenfold difference in specific ionization.

The results of this investigation will be published in detail elsewhere[7]. We are indebted to the National Cancer Institute of Canada and the Saskatchewan Cancer Society for generous support of our studies.

New Hydroxamic Acids as Antitubercular Agents

PREVIOUSLY, one of us suggested using salicylhydroxamic acid as an antitubercular agent[1]. The substance was subjected to clinical examination by another of us (S. H.) and showed promising results in fifteen cases of pulmonary tuberculosis. The substance was well tolerated by the patients, when large doses of 10–20 gm./day were administered.

This led one of us (T. U.) to look for more potent derivatives of salicylhydroxamic acid. Eventually, a number of derivatives of it were prepared. Some of them, for example, 3-bromosalicylhydroxamic acid ('*T* 40'), 2-hydroxy-3-methyl-benzhydroxamic acid (2,3-cresotinohydroxamic acid, '*T* 95'), 2-hydroxynaphtho-3-hydroxamic acid ('*T* 106'), 2-hydroxyquinoline-7-hydroxamic acid ('*T* 139'), proved to be more potent *in vitro* than salicylhydroxamic acid. All these substances are new to the literature.

5-Bromosalicylhydroxamic acid (m.p. 232°) was prepared by direct bromination of salicylhydroxamic acid in acetic acid medium and purified by crystallizing from alcohol[2]. 2,3-Cresotinohydroxamic acid (m.p. 148°–150° decomp.), 2-hydroxynaphtho-3-hydroxamic acid (m.p. 191°–192° decomp.) and 8-hydroxyquinoline-7-hydroxamic acid (m.p. 208°–209° decomp.) were prepared in the conventional way by the action of hydroxylamine on methyl esters of 3-cresotic, 2-hydroxy-3-naphthoic and 8-hydroxyquinoline-7-carboxylic acids respectively. Details of their preparation will be reported elsewhere[3].

The bacteriostatic concentration *in vitro* of these substances against saprophytic mycobacteria was found to be:

Table 1

Sodium salts of *T* 40	of *T* 95	of *T* 106	of *T* 139
15–30	15–75	8–16	2–4 mgm. per 100 ml.

Their toxicity to rats (lethal doses expressed in gm. per kgm. body-weight) is shown in Table 2.

Table 2. Lethal doses (gm./kgm. body-weight)

Substance	*per os*	Subcutaneous	Intravenous
T 40	c. 3·5	0·8	0·12
T 95	c. 3·0	0·6	0·15
T 106	c. 2·0	(insoluble in water)	
T 139	c. 2·0	0·5	0·03

Besides the toxicity control, the products have been examined as to their pharmacological activities on different organs. The experiments showed only a very weak action upon the animal organisms.

Experiments *in vivo* with '*T* 40' were carried out by using guinea pigs (*c.* 500 gm.) inoculated intraperitoneally with 0·1 mgm. of *Mycobacterium tuberculosis* ($H_{37}Rv$ strain). Administration of the drug started on the eighth day after inoculation and lasted for forty-two days. Thirty-five days later the animals were killed and the extent of tuberculous involvement was examined. The results are shown in Table 3.

Table 3

Substance	No of animals	Daily dose (mgm. per animal)	Administration	Mortality	Average tuberc. index	Average survival time
'*T* 40'	20	10	subcut.	4 (20%)	65	80·2
Streptomycin	20	10	,,	2 (10%)	57	84·4
Control	20	—	—	18 (90%)	100	47·2

Similar results were obtained with '*T* 106', the mortality being only slightly greater than that of the animals treated with streptomycin. The results with '*T* 95' were less favourable[4].

The action of bromosalicylhydroxamic acid on human tuberculosis was then investigated clinically. 1 gm. a day was administered in twenty-five cases for periods of 25–102 days; a total of 25–100 gm. was administered in each case. The drug was well tolerated even if the dose was increased to 2 gm. Particularly interesting were nine cases of tubercular meningitis, which did not appear to be influenced by streptomycin. The additional administration of '*T* 40' in most of these cases produced a considerable improvement. The results are shown in Table 4.

Table 4

	After administration of '*T* 40'; number of cases				
	Very great improvement	Considerable improvement	Marked improvement	No improvement	Worsening
Tubercular meningitis unsuccessfully treated with streptomycin	1	4	2	1	1
Miliary tuberculosis		1	2		
Infiltrative pulmonary tuberculosis		2	2	1	2
Chronic cavernous tuberculosis			1		3
Pleurisy with effusion and diffuse tuberculosis	1				

Of twenty patients showing radiologically tuberculous lesions in the lungs, nine showed a pronounced improvement of the radiological picture (two of them very considerable improvement), eight showed no improvement, and three became worse.

Some of the patients resistant to '*T* 40' have been treated with streptomycin; no improvement followed[5].

Survival of the Perfused Cat's Brain in the Absence of Glucose

In recent experiments in which the cat's brain was perfused through the isolated cerebral circulation with glucose-free 'simplified blood', brain functions were maintained for well over an hour if the rate of flow of blood was kept high. In previous perfusion experiments with glucose-free blood, the vascular resistance in the brain usually rose, reducing the rate of flow of blood considerably, with consequent loss of physiological activity of the brain and reduction of its oxygen consumption after 10–15 min. of glucose-free perfusion. When glucose was added afterwards to the blood, it was not taken up by the brain unless fresh liver extracts were also added[1].

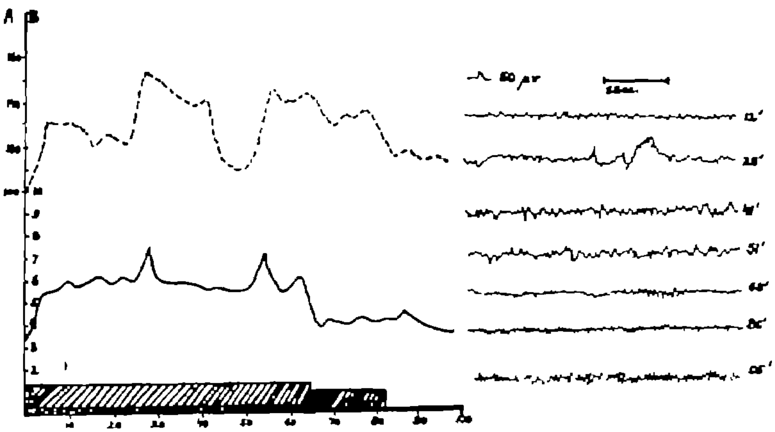
In the present experiments the technique of isolating the brain circulation and the method of perfusion were similar to that described previously[2]. Special care was taken to avoid contamination of the perfusion blood with the cat's systemic blood. Thiocyanate injected into the cat's circulation did not enter the perfusion blood. In some experiments all the extracranial soft tissue was removed from the head. These experiments gave results identical with those in which this precaution was not taken. Brain samples weighing 100–200 mgm. were excised during perfusion for analysis.

The bovine blood corpuscles used for perfusion were washed with 30–60 volumes of Ringer's solution containing penicillin, and 35 parts were suspended in 65 parts of a medium containing 7 per cent bovine serum albumin (Armour and Co.), 0·9 per cent sodium chloride, 0·044 per cent potassium chloride, 0·19 per cent sodium bicarbonate, 0·037 per cent calcium chloride, 0·038 per cent magnesium sulphate, and 0·021 per cent potassium dihydrogen phosphate. This 'simplified blood' was saturated with 5 per cent carbon dioxide in 95 per cent oxygen. A flow of 100–250 ml. per min. of blood for 100 gm. of brain was maintained.

Brain activity. A typical electro-corticogram is reproduced. In some experiments rhythmical electrical activity was still discernible after 90 min. of perfusion. The corneal reflex, respiration and vasomotor activity persisted for 60–100 min. The response to afferent stimulation of the sciatic nerve could be recorded from the cortex for a similar period of time. Addition of 'Metrazol' to the perfusion blood 40 min. after the start of perfusion caused convulsions which could be repeated; 3 mgm. of 'Nembutal' added to the perfusion blood at its entrance to the brain after 50–60 min. of perfusion extinguished the electro-corticogram within a few seconds and the corneal reflex and respiration shortly afterwards.

Oxygen consumption. During the present glucose-free perfusion experiments, oxygen consumption was very nearly as high as in other experiments in which glucose was present in the 'simplified blood'[2]. The usual rates were 5–7 ml. oxygen per 100 gm. brain per min. The total amount of oxygen consumed by the brain during the first hour of glucose-free perfusion exceeded by several times the amount necessary for the oxidation of the carbohydrates available at the start of the perfusion in the brain. During metrazol convulsions, even when 'Metrazol' was administered 50–60 min. after the start of glucose-free perfusion, the rate of oxygen consumption increased two- to three-fold. 'Nembutal' in a concentration of 3 mgm. in 100 ml. blood decreased the oxygen consumption only slightly. The respiratory quotient of the brain was 1·00 at the outset and decreased as perfusion progressed. Values as low as 0·50 were found frequently, even though the oxygen consumption remained high.

The glucose content of the brain was usually very low or dropped to zero after 10 min. of perfusion. In most experiments a small amount of glycogen remained in the brain throughout. A slight increase of glycogen in the brain was also found in some cases towards the end of the perfusion period. The concentration of lactic acid in the brain decreased gradually during perfusion, contrasting in this respect with similar experiments in which the perfusion blood contained glucose[3]. The potassium concentration in the brain decreased gradually and the sodium concentration increased during perfusion. Thus in some cases during prolonged perfusion experiments while



Typical glucose-free perfusion experiment. Ordinate: *A*, blood flow; *B*, oxygen consumption, ml. per 100 gm. of brain per min. Abscissa: perfusion time in minutes. The figures next to the electrocorticograms show perfusion times in minutes

No. of experiments	Perfusion time (min.)	ml. per 100 gm. brain per min.		R.Q.	mgm. in brain			Oxygen consumed by 100 gm. brain in 1 hr. (ml.)	Oxygen not accounted for by carbohydrates (ml.)	Electrocorticogram	Cortical response to afferent stimulation	Respiration	Corneal reflex
		Blood flow	Oxygen consumed		Glucose	Glycogen	Lactic acid						
9	20	165 (115–215)	6·4 (4·8–8·0)	0·75 (0·54–0·90)	4 (0–10)	18 (0–42)	148 (80–216)	407	325	+	+	+	+
9	40	170 (125–220)	5·8 (3·4–7·5)	0·80 (0·34–0·89)	3 (0–6)	18 (6–37)	88 (25–133)			+	+	+	+
8	60	168 (90–220)	5·2 (3·2–6·5)	0·72 (0·51–1·05)	3 (0–10)	20 (14–30)	65 (16–115)			+	+	+	+
4	80	142 (115–190)	4·1 (2·7–5·5)	—	3 (0–7)	27 (20–34)	69 (68–70)			+	+	+	+
2	100	127 (120–135)	3·7 (3·2–4·2)	0·80	7 (0–15)	37 (34–42)	85 (81–90)			+		+	+

The figures in brackets show the lowest and highest values found.

the brain was still active, the concentration of sodium in the brain was higher than that of the potassium.

The non-protein nitrogen in the blood and in the brain increased only very slightly during perfusion.

The observations, which are summarized in the accompanying table, show that the brain continues to function in the absence of glucose, if the rate of flow of blood is high. Presumably substances other than glucose or glycogen are oxidized, while oxygen consumption is maintained at about the same rate as in the presence of glucose. Under these conditions the brain maintains for well over an hour rhythmic electric activity and the ability to respond to chemical or afferent stimulation.

Necessity of Boron for *Nostoc muscorum*

There are very few reports on the necessity of boron for the growth of lower plants. Koffler *et al.*[1] found that borax increased the penicillin yields of submerged corn-steep cultures of *Penicillium* as well as cultures of *Penicillium* in synthetic medium. No definite requirement by algæ for boron has yet been shown[2].

I wish to report that *Nostoc muscorum* grown in Corning (boron-free) flasks in media free from boron requires boron. The boron-free cultures showed a relatively small reduction in cell count and a chlorosis which started slowly during the third week; they became completely white by the end of eight weeks. The reduction in cell count for an eight-week growth period was 39 per cent for cultures grown at a light intensity of 100 ft.-c. and at a temperature of 32–34° C. Since appreciable boron is transferred through the inoculum, it was found best to use an inoculum which itself was boron-free. The boron-deficiency chlorosis was corrected by the addition of boron. One fairly old boron-deficient culture had become acidic and also had to be made alkaline in order to transform the culture into one with a normal green colour. A detailed study of *p*H and boron-deficiency failed to establish any relationship between the deficiency and a trend toward higher hydrogen-ion concentration.

Cultures grown in Corning flasks with boron added or in 'Pyrex' flasks with or without boron added did not show similar chlorosis. The optimum boron concentration appeared to be about 0·1 p.p.m. Concentrations greater than 1 p.p.m. were toxic, as indicated by a yellowing and a reduced growth. There was very little or no growth at 100 p.p.m. and more.

The cultures of *Nostoc muscorum* were bacteria-free pure cultures, and were originally obtained from Dr. Folke Skoog and Dr. G. C. Gerloff, of the University of Wisconsin. They were grown according to the method of Chu (formula number 10)[3].

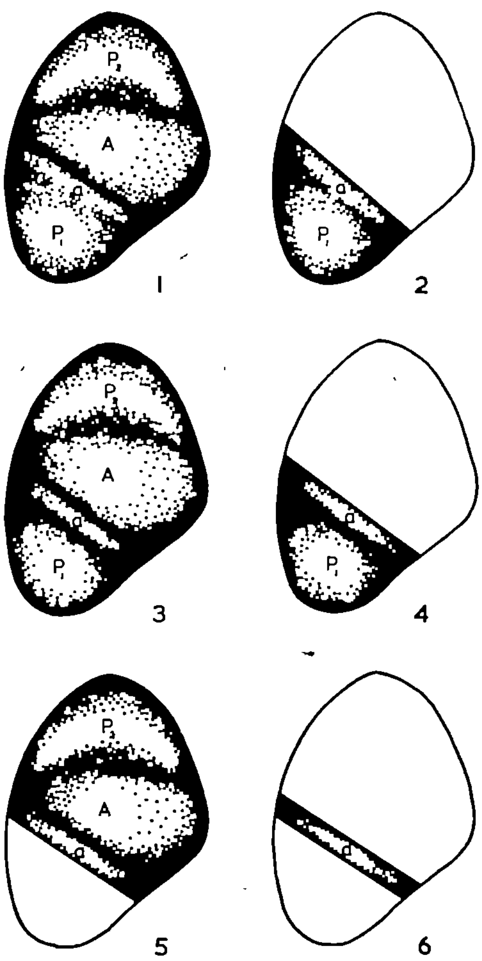
Regeneration of the Potato Shoot Apex

The apical meristem of the shoot in most species of plants is domed above the insertion of the leaf primordia, and its flanks slope symmetrically from the summit to the regions where differentiation is proceeding. When the distal cells in the apical meristem of ferns[1,2] or angiosperms[3,4] are punctured, regeneration of the flanks is promoted. From such experiments it has been concluded that physiological dominance within the apical growth field is an attribute of a small number of cells situated at the distal extremity of the apical meristem[5]. It is appropriate, therefore, to inquire as to the mechanism by which the form of the meristem is preserved. The persistence of such form is the earliest and most fundamental expression of morphogenesis in the shoot, the subsequent morphological developments being conditional on the continued orderly growth of the apical meristem.

As part of a larger series of experiments planned to shed light on this problem, a small panel of meristematic tissue which formed part of the apical flank just distal to P_1, the youngest emergent leaf primordium, that is, just above its axil, was isolated in various ways from either or both P_1 and the remainder of the apical meristem (*A* in Figs. 1–6). It was thereby hoped to isolate the panel *a* from possible hormonal and nutritional competition from P_1 and the apical meristem. From other experiments it was known that there is lateral and acropetal, apolar, transmission of a hormone-like stimulus



Figs. 1–6 Illustrating diagrammatically the apex immediately after the operations. Numbers correspond with those of treatments 1–6 in the table, and the conditions it was hoped to establish in each treatment are indicated there

within the limits of the apical meristem, but coincidental with tissue differentiation the stimulus is transmitted in a strictly basipetal, polar, direction. The incisions were therefore made sufficiently deep to penetrate all the meristematic layers, but not so deep as to interfere with the nutrient supply in the subapical region. Such incisions preclude hormonal inhibition of growth in the panel *a*. Nutritional competition, and the effects of substances which diffuse without polarity from P_1 or the apical meristem, may be prevented by excising one or both of the competing regions.

Results of the six treatments are presented in the accompanying table. Regeneration of the panel *a* involves the formation of a small new apical meristem, the records being made when the first leaf became emergent on it. Casual leaf inception, unrelated to apical activity, was never observed. The results of treatments 3 and 4 are closely comparable to those of treatments 1 and 2 respectively, because, whereas the incision isolating *a* from *A* always gaped, that between *a* and P_1 became compressed and the cut surfaces regrafted. It has not yet been possible to introduce impermeable substances into the incision without damaging the panel.

In treatments 1, 3 and 5 twenty-one of sixty panels regenerated one or two leaves each. None continued to grow further, but remained in an inhibited but embryonic state on the stem flank. Excision of P_1 increased the number of panels on which leaves emerged, not directly, by facilitating leaf inception, but by promoting a more rapid growth of the panel along its proximal–distal axis.

In treatments 2, 4 and 6 nearly all the panels regenerated, and regeneration commenced before that in the other three treatments. P_1, when present, was able to to retard the growth of the panel temporarily, but was unable to inhibit it entirely.

On this evidence the regulation of growth on the flanks of the apical meristem is apparently dependent mainly on the activity of the apical meristem itself, that is, the apical meristem is a self-regulatory field of growth. Hormonal inhibition of growth appears to be of relatively little importance, nutritional competition being the factor limiting regeneration in these experiments. Leaf primordia exert a transitory and localized inhibitory action on the growth of the apical flank, which is indicated by a flattening of the apical surface just distal to the insertion of a leaf. Since inhibition of regeneration by P_1 is strongest before the maximum rate of growth of this leaf is reached, it may be suggested that nutritional competition is of a rather specialized type, confined perhaps to requirements for the growth of meristematic tissues.

Ball[6] has shown that when the apical meristem of *Lupinus* is divided into six sectors all may regenerate, and has concluded that this is the minimal area able to regenerate in this species. In the present experiments the isolated panel was equal in area to one-sixth of the apical meristem. There were four cells along the proximal–distal axis of the panel, and twelve to fifteen along the tangential axis.

Smaller panels, obtained by incising the panel *a* at right angles to the first incisions, have been caused to regenerate by excision of the remainder of the apical meristem. Regeneration occurred whether or

Regeneration of the isolated panel *a* during six days. 20 shoots were used in each treatment. In column 1, H and N refer to hormonal and nutritional competition respectively of the apical meristem *A* and P_1. + and − indicate whether or not such competition is occurring. Ra = regeneration of panel *a*, and L = the total number of leaf primordia on 20 panels of each treatment. The final column gives the average number of leaves on a panel after six days

Treatment		Day 2		Day 3		Day 4		Day 6		$\frac{L}{20}$
		Ra	L	Ra	L	Ra	L	Ra	L	
1	−HA +NA +HP$_1$ +NP$_1$	0	0	0	0	3	3	3	3	0·15
2	−HA −NA +HP$_1$ +NP$_1$	0	0	7	7	14	21	20	52	2·6
3	−HA +NA −HP$_1$ +NP$_1$	0	0	0	0	2	2	5	6	0·3
4	−HA −NA −HP$_1$ +NP$_1$	0	0	7	7	14	23	18	43	2·15
5	−HA +NA −HP$_1$ −NP$_1$	0	0	0	0	8	10	13	16	0·8
6	−HA −NA −HP$_1$ −NP$_1$	2	3	14	18	20	38	20	63	3·15

not a part of P_1 was left attached. The smallest pieces of apical tissue which regenerated had only twelve cells in the superficial layer, and were equivalent to not more than one-twentieth of the area of the apical meristem. The vascular system of such regenerated shoots was invariably solenostelic.

On two occasions out of 123 very small apical panels failed to regenerate as shoots, but underwent a limited amount of growth, developing as centric organs similar to those previously obtained by isolating a presumptive leaf position from the apical meristem[7].

The experimental evidence presented here indicates that very small groups of superficial cells of the apical meristem are able to regenerate a shoot, providing they are freed from the competition of other regions of the apical meristem for the supply of available nutrients from the subapical region, and that such competition between different regions of the apical meristem is one of the regulatory mechanisms by which the form of the apical meristem is preserved.

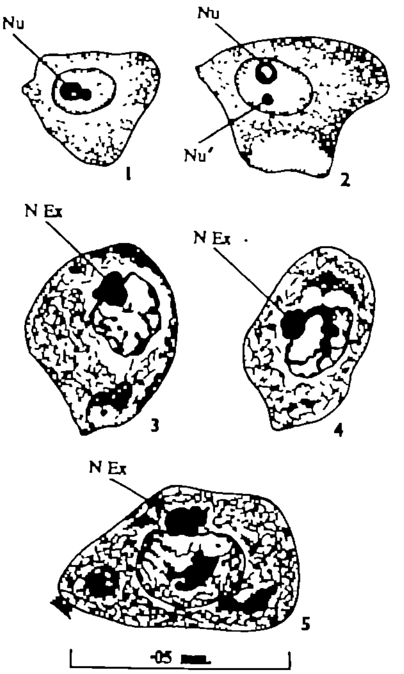
Extrusion of Nucleolar Material in the Female Germ-Cells of *Lumbricus terrestris* L.

So far as I am aware, the extrusion of nucleolar material into the cytoplasm has not been recorded for the female germ-cells of *Lumbricus* or any other earthworm. In this connexion, Harvey[1] remarked that in the nuclei of the "nearly ripe oocytes there may occur little droplets of material, similar in reactions to the plasmosome. They may be lying on the surface of this body, or may be entirely separate. Occasionally they are seen on the nuclear membrane, but never outside it. This may point to extrusion of nucleolar fragments, but only on a very small scale and never into the cytoplasm". Gatenby and Nath[2] observed that: "Neither Harvey nor the present writers have found any satisfactory evidence of nucleolar emission in *Lumbricus*".

My preparations of the ovaries of *Lumbricus*, fixed in Bouin's fluid and stained with Ehrlich's hæmatoxylin or iron-hæmatoxylin, show convincingly that extrusion of nucleolar material takes place. The nucleolus is stained a purplish colour with Ehrlich's hæmatoxylin. Often the nucleus contains two nucleoli, and in such cases the larger one contains one or more lightly stained droplets, while the smaller body appears to be homogeneous (Figs. 1 and 2); the latter seems to originate from the large nucleolar body (Fig. 1) and is ultimately extruded into the cytoplasm. After iron-hæmatoxylin, the nucleolus and nucleolar extrusion are uniformly black throughout.



Oocytes of *Lumbricus terrestris* from sections of ovary fixed in Bouin and stained with Ehrlich's hæmatoxylin (Figs. 1–2) or iron-hæmatoxylin (Figs 3–5).
Nu., nucleolus; *Nu'.*, smaller nucleolus; *N Ex.*, nucleolar extrusion

The nucleolar material which is extruded into the cytoplasm takes the form of a large, spherical nucleolus-like body which seems to press against the nuclear membrane and gradually passes into the cytoplasm, where finally it breaks up into smaller particles. The process appears to take place repeatedly, as I have observed it in oocytes of different sizes. Figs. 3 and 4 show two stages in the emission of nucleolar material; in Fig. 3, a nucleolar extrusion has passed half-way through the nuclear membrane, while in Fig. 4, an extrusion in another oocyte lies almost wholly in the cytoplasm. In Fig. 5, a similar body is shown in the cytoplasm, and already shows signs of breaking up into smaller pieces.

The presence of nucleolar extrusions in the female germ-cells of many animals has previously been described. Among annelids, the classical example of *Saccocirrus*, recorded by Gatenby[3], is well known. Unlike *Saccocirrus*, however, the extrusions of *Lumbricus* are large, spherical bodies resembling a nucleolus; in fact, in this animal the nucleolar extrusions more closely resemble those of *Libellula depressa* described by Hogben[4]. The presence of nucleolar extrusions indicates that the female germ-cells of *Lumbricus*, and probably those of other earthworms, are much more complex structures than supposed by previous workers such as Nath and his collaborators[2,5,6].

I wish to express my thanks to Prof. R. A. R. Gresson, for guidance and valuable help.

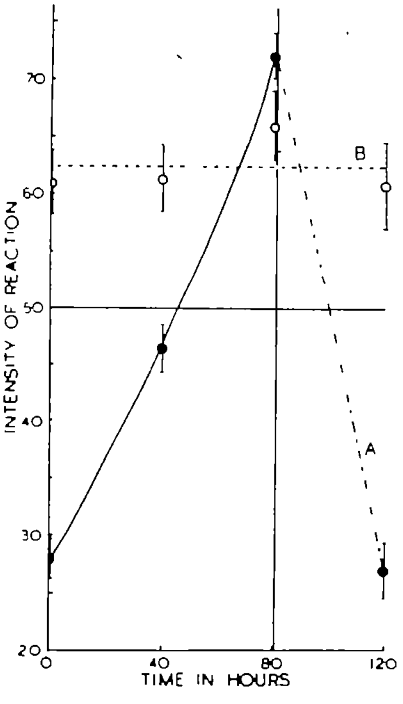
Effect of Desiccation on the Humidity Response of *Tenebrio*

THE ecological significance of an experimentally demonstrated and strongly marked preference for low humidities shown by certain arthropods has recently been discussed by Smith[1]. *Tenebrio molitor* L. is one insect the behaviour of which in humidity gradients has been fully studied and which shows a well-defined dry preference[2-4]. In laboratory cultures of adult *Tenebrio*, however, we have frequently observed that, if a wad of wet cotton-wool be placed in the culture dish, the animals rapidly accumulate on the wool and drink. It is thus clear that the dry preference does not express itself in all conditions.

We have investigated the effect of desiccation upon the intensity of the humidity response of this insect, using a technique similar to that employed by Gunn and Pielou[2]. All experiments were carried out at 25° C. under artificial light and with a gradient of 93–44 per cent relative humidity. Animals from stock cultures maintained at the experimental temperature were placed in dishes containing damp cotton-wool for a period of 12 hr.; the intensity of their humidity preference was determined and they were then desiccated over calcium chloride. The intensity of their response was redetermined after 40 and 80 hr. At the end of this period the animals were returned to the dishes containing the damp cotton-wool and, after a period of 40 hr., their response was again assessed. The results obtained are shown in curve *A* of the accompanying graph, which is based upon seven independent experiments.

It will be seen that there is a change in the humidity preference as the desiccation proceeds. Once the animals are allowed renewed access to water, the original dry preference is shown. There is no significant difference between the reaction intensities of watered animals before and after the period of desiccation. This eliminates the possibility that starvation has contributed to the changing pattern of humidity behaviour, as has been found by Willis and Roth[5] in *Tribolium*.



Effect of desiccation upon the humidity preference of adult *Tenebrio*. Black circles, normal animals; open circles, animals without antennæ. Reaction intensities of less than 50 indicate a dry preference, greater than 50 a wet preference. The lines running through the points indicate twice the standard errors of the mean values

Gunn and Pielou were able to show that the receptors responsible for the initiation of the dry preference of *Tenebrio* lay in the antennæ. Over a short gradient of 100–94 per cent relative humidity they found no response to humidity by animals lacking antennæ. We have been able to confirm this observation. We find, however, that with the wide gradient of 93–44 per cent relative humidity a wet preference is exhibited. The intensity of this preference is but slightly affected by desiccation. Although the intensity of the final wet preference of normal desiccated animals is slightly greater than that of comparable animals without their antennæ, we are unwilling to conclude at the moment that any specific sense organs concerned with a wet preference lie on the antennæ. It is clear, however, that such sense organs must exist elsewhere on the body.

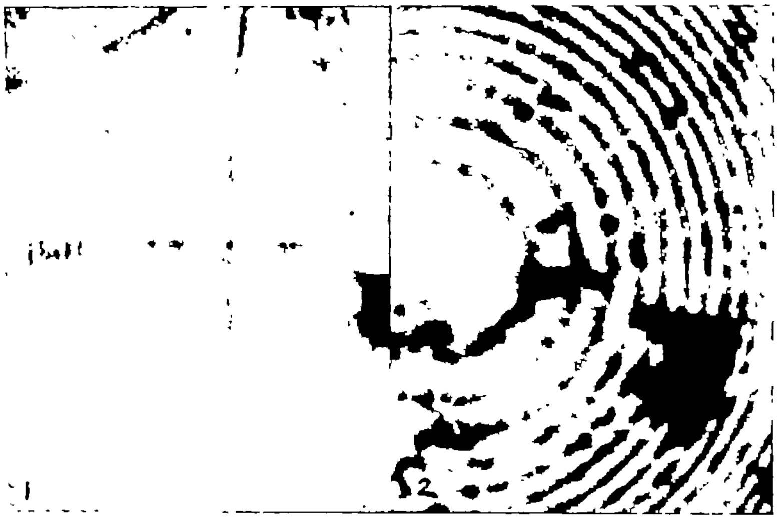
Evaluation of Small Radii of Curvature using the Light-Profile Microscope

THE light-profile microscope described by Tolansky[1] is being applied in this laboratory to several fields, including the study of features of crystal growth[2], the measurement of the thickness of thin film[3] and evaluation of amplitudes of oscillation[4]. In this communication a brief description is given of a further application, whereby the radii of curvature of small spheres, droplets, cavities, etc., can be readily measured.

When the light profile passes over a curved surface, a curved profile line appears in the field of view, a spherical surface leading to a profile which approximates to part of an ellipse, the eccentricity of which is determined by the ratio of the magnifications in extension and in depth. From the curved profile and the known magnifications, the curvature of the surface can be evaluated. (Depending on the flatness of field of the particular objectives available, it may in individual cases be necessary to determine field curvature and correct for this—an easy matter.)

The reliability of the procedure has been tested by using it on a steel ball-bearing of radius 0·6 mm., for with such an object Newton's rings can readily be obtained to give a precise local value of curvature Furthermore, a principal advantage of the light profile is the availability of high power. The stee ball was placed on a cover slip and examined with λ 5,461 at × 875 (4-mm. objective). Newton's ring are seen in Fig. 2. Fig. 1 shows the light profile a × 450 in extension. The optical arrangement suited to the light profile is not the best for interferometry



hence Newton's rings can be seen only faintly, superposed on the profile. The radius of curvature calculated from the interference fringes is 0·596 mm. and from the profile 0·595 mm., the estimated error in the latter being some ± 1 per cent (that is, ± 0·005 mm.).

There is, then, complete confirmation of the reliability of the light-profile method, particularly for measuring curvature of small bodies or small cavities. Spherical cavities, such as those produced in micro-indentation by spheres or ball-ended diamonds, erosion pits, cavities produced by spark discharges on metals, etc., are but some of the features now under examination.

Thermionic Constants of the Iron Group of Metals

In a recent communication[1], we gave an account of a new method of determining the thermionic constants of graphite, which is based on the determination of the saturation vapour pressure of the electron gas in equilibrium with the substance at different known temperatures, and application of the well-known thermodynamic relation of Clausius and Clapeyron. In the actual experiments, the saturation vapour pressure of the electron gas in a graphite chamber is determined by finding the rate of effusion of the gas into vacuum through a small hole in a thin wall of the chamber. The chamber is in the form of a thin-walled tube, and can be heated to any desired high temperature by sending a suitable heavy electric current through it. In order to eliminate the electrons emitted by the graphite surface adjoining the effusion hole, the surface is covered by a thin sheet of mica, with a small hole punctured in it; this comes just in front of a bigger one in the graphite wall and serves as the effective effusion hole.

This method of determining the thermionic constants, and in particular the coefficient *A* in Richardson's equation, has advantages over the other methods, since it is insensitive to the usual type of contamination of the emitting surface; and further, it does not require a knowledge of the effective area of the emitting surface or of the reflexion coefficient of the electrons at the surface.

The inner walls of the graphite chamber, as also the regions close to the effusion hole, can be coated suitably with other metals, and the method can thus be used for the determination of the thermionic constants of these metals also. We have determined in this manner the thermionic constants of chromium, iron, cobalt and nickel, depositing the metals both electrolytically and by evaporation from a tungsten wire coated previously with the metal, or carrying small rings of the metal. The results were found to be independent of the method used for the deposition of the metal and were reproducible.

The observations fit well with Richardson's equation:

$$i = AT^2 \exp(-\varphi/kT), \qquad (1)$$

in which *A* and φ are independent of temperature, and have the values given in the accompanying table.

Metal	φ (eV)		*A* (amp cm.$^{-2}$ deg.$^{-2}$)	
Chromium	4·58	±0·02	60	±2
γ-Iron	4·31		60	
Cobalt	4·41		60	
Nickel	4·50		120	±5
Note added in proof, October 8.				
Titanium	3·95		44	
Vanadium	4·12		50	
Manganese	3·83		34	

As is well known, the observed fit of the experimental data with formula (1) with temperature-independent constants *A* and φ cannot be regarded as excluding a small linear variation of the actual work function with temperature, since such a variation will be equivalent to a temperature-independent change in *A*. Apart from the normal thermal expansion of the metal, which will lead to a small temperature variation of the work function, there is a further source of such variation in these metals. The *d*- and the *s*-energy bands of these metals overlap, the former being nearly full, and having a much larger density of energy-states than the latter. As a result, (1) the electronic specific heat in the condensed phase will be considerable, and (2) on change of temperature there will be a transference of electrons from one band to the other, and a consequent change in the work function[2]. Hence experimental data for the thermionic constants of the transition elements are of special interest.

γ-Rays of Radium-D

A Cauchois type of curved crystal spectrometer[1] has been employed to study the γ-radiation from radium-D using a 100-mC. source.

The source was produced at the Radiochemical Centre, Amersham, by anode deposition on a dished platinum foil of area $\frac{1}{4}$ sq. in. The total weight of inactive deposit was 2·1 mgm. An aluminium foil of thickness 0·05 mm. was sealed over the source. The β-particles of radium-E were absorbed in a filter-paper screen of superficial mass 0·45 gm./cm.^{2}.

The γ-spectrum was recorded on Ilford G 5 nuclear plates coated to a thickness of 200 μ. The developed plates were scanned by microphotometer and the resulting observations were corrected for absorption before the photographic plate and for variation of the sensitivity of the photographic plate with wavelength. Exposures of 700 hr. were made, covering at full aperture the energy ranges 62–19 keV. and 50–16 keV. The well-known γ-ray was found at 265·96 ± 0·13 X.U. or 46·52 ± 0·02 keV., in good agreement with earlier observations[2] recalculated on the basis of recent values of the physical constants[3]. No other γ-ray was observed between the upper limit of observation at 62 keV. and the upper limit of the L X-ray spectrum of radium-E ($L\gamma_4$) at 16·2 keV. γ-Rays within this region have been reported by various authors[4,5], though inconclusive or negative results have been obtained by others[6].

The upper limits set by our observations to the intensities of the γ-rays reported by Tsien[4] relative to the intensity of the 46-keV. line are as follows:

Energy of γ-ray (keV.)	46·5	42·6	37	31	23·2	16·1
Relative intensity	1	≤0·015	≤0·015	≤0·015	≤0·025	≤0·06

A full account of the experimental technique and of other measurements will be published at a later date.

The mica crystal used in this work was kindly given by Prof. S. Tolansky. A further gift of mica crystals from Dr. J. M. Rayner is gratefully acknowledged. The work was sustained for two years by a grant from the Department of Scientific and Industrial Research to one of us (G. T. E.).

Growth Spirals and their Relation to Crystal Habit as Illustrated by Apatite

The observation of growth spirals, as predicted by the theory of Burton, Cabrera and Frank[1], on prism faces (10$\bar{1}$0) of apatite crystals, has been reported earlier[2]. We have now observed completely differently shaped growth spiral patterns on tabular colourless apatite crystals from Sulzbachtal (Austria), which have probably grown from solution. The accompanying photograph (Fig. 1) shows one of the observed patterns. The direction of the c-axis is vertical. The shape and orientation of the spiral are the same in all cases. The dominating system consists of two co-operating spirals, which dominate several other dislocations of equal and of different strengths. In the latter case the formation of residual steps is noticed. Interlacing occurs in one direction. The main growth-fronts have a step-height of 140 ± 20 A.

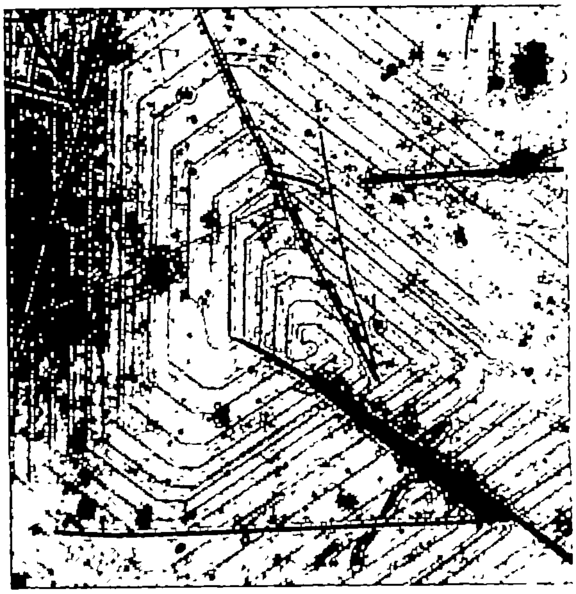

Fig. 1

By introducing a two-dimensional reference system with the apatite parameters $c : a = 0·73 : 1$ as units, indices similar to the Miller indices for planes can be given to the growth fronts. These are, respectively, 01, 11, 10, 1$\bar{1}$, 0$\bar{1}$, $\bar{1}\bar{1}$, $\bar{1}$0 and $\bar{1}$1. Perpendicular to these directions we consequently have eight sharp minima for the growth velocity, and the following relations exist: $v_{10} > v_{01} = v_{0\bar{1}} > v_{\bar{1}\bar{1}} = v_{\bar{1}1} > v_{\bar{1}0} > v_{11} = v_{1\bar{1}}$. The subsequent polar diagram has only a line of symmetry perpendicular to the c-axis, which is consistent with the crystal class of apatite. The spirals are oriented in the same way on the six prism faces, proving the presence of a hexad symmetry axis.

When comparing the shape of the spirals described earlier and the shape of the present ones with respect to the habit of the crystals, a striking similarity will be noticed between the outline of the prism faces and the shape of the spiral growth fronts. This relation is shown schematically in Fig. 2, where (a) represents

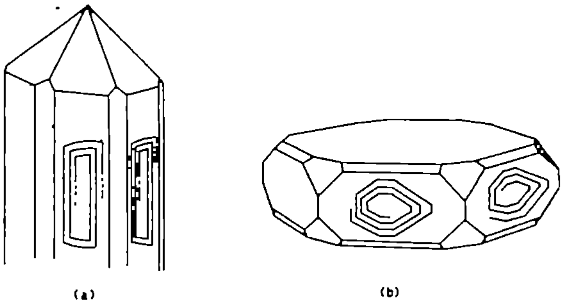

Fig. 2

a prismatic crystal (Jumilla) and (*b*) a tabular crystal (Sulzbachtal), with their respective growth patterns.

As one can scarcely imagine an influence of the edges of the prism faces upon the growth fronts and imposing their outline to them, one must rather accept the contrary, that is, that crystal habit results from the shape of the growth spirals. Agents changing the relative growth-rates of growth fronts would influence crystal habit in such a way that edges will be developed perpendicular to directions of minima for growth velocities on the close-packed faces.

These observations further support the idea that habit modification by foreign substances would proceed rather by selective adsorption along growth fronts than by adsorption on certain crystal planes.

I wish to thank Prof. W. Dekeyser for his kind interest, the C.N.B.C.P.M. for support, and the Mineralogy Department of Koninklijk Belgisch Instituut voor Natuurwetenschappen (Brussels) for the loan of specimens.

Determination of the Pore-Size Distribution in Porous Metal Bodies

The pore-size distribution of a porous metal body can be defined in three ways, namely, those given by the expressions $\partial V/\partial r$, $\partial\alpha/\partial r$ and $\partial N/\partial r$, where r is the 'radius' of the pore and ∂V, $\partial\alpha$ and ∂N respectively represent volume, permeability and number of pores associated with the pore-size interval r to $(r + \partial r)$. $\partial V/\partial r$ may be determined by observing the capillary rise of a liquid in a narrow strip of the material. If h is the capillary rise, a simple equation relates h to r, and $\partial V/\partial h$ is readily determined by breaking the strip at h_1, h_2, h_3 . . . and weighing the pieces to ascertain the values of V corresponding to the sections $(h_1 - 0)$, $(h_2 - h_1)$, $(h_3 - h_2)$. . . .

If the perimeter of a section through a pore is P and the area of the section A, then equating forces acting on the surface of the liquid that has risen in the pore and neglecting the weight of the liquid above the meniscus, we may write:

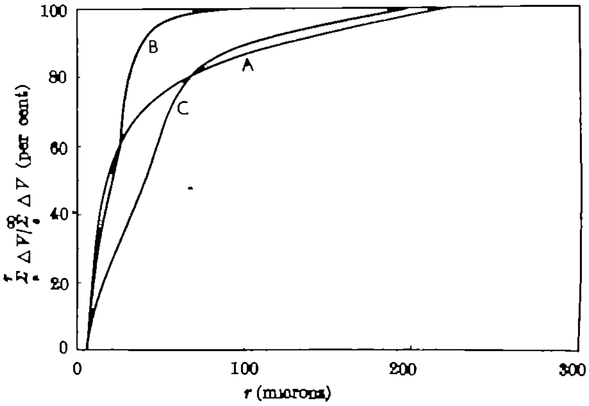
$$P\sigma\cos\beta = Ahdg,$$

where σ is the liquid-air interfacial tension and β is the angle of contact between the liquid of density d and the material from which the porous body is made. The value for A/P thus determined is equal to $r/2$ if the pores are circular in section; it is therefore implied in the sequel that the 'radius' of a pore (r) is that calculated as $2A/P$. This is in error inasmuch as the pores are not circular in section.

The smallest pore that can be determined by a capillary rise method has a 'radius' given by

$$r = \frac{2\sigma\cos\beta}{X},$$

where X is the atmospheric pressure. In order to extend the determination of the distribution of pore size to the very smallest pores, it is therefore necessary to use a liquid of very low surface tension to fill them.



(*A*) and (*B*), pores filled with water; (*C*), pores filled with acetanilide

The values of h corresponding to the values of r (5–250 μ) which commonly occur in metallic filter materials are inconveniently large if water is used as the pore-filling liquid and rises against the force of gravity.

Increasing g by means of a centrifuge enables a determination of the distribution of the pore-sizes from 7 to 250 μ (which contain more than 99 per cent of the total pore volume) to be made on a piece of porous stainless steel 10 cm. × 1 cm. × 0·3 cm. The accompanying graph shows three typical pore-size distribution curves of samples of porous stainless-steel filter materials. Curves *A* and *B* were determined by centrifuging the porous sample in the presence of a slight excess of water, which was thus distributed in the pores under the mutually opposing forces of surface tension and increased gravity. An addition of liquid oxygen by means of a specially designed funnel was made, to freeze the water in the pores while the centrifuge was still spinning. The specimen was then broken at the points h_1, h_2, h_3 . . . into previously weighed weighing bottles before the ice melted. After weighing, the water was removed from the broken pieces in an oven at 110° C. and the broken pieces reweighed to determine their water contents.

Organic compounds may also be used as pore-filling liquids. As an example of their use, the results plotted as curve *C* were determined with acetanilide. A small furnace was mounted in one of the centrifuge tubes, slip rings providing the means of carrying the heating current to it and the thermal E.M.F. from it to a pyrometer. Molten acetanilide (melting point 114° C.) was allowed to distribute itself through the pores of the metallic compact under the forces of its surface tension and the increased g due to centrifugal forces. On being allowed to cool, it solidified in position and its distribution through the metal could be determined in a manner similar to that used for the ice-filled porous metal.

A full account of this work is being prepared for publication elsewhere.

I wish to acknowledge the help of Mr. K. Simpson, who did part of the experimental work; and to thank Mr. D. A. Oliver, director of research to the B.S.A. Group of Companies, for his encouragement and support of this work.

Stability of Lyophobic Sols

ACCORDING to Verwey and Overbeek[1], the coagulation value of various electrolytes for aqueous sols is given by:

$$c = 8 \times 10^{-22}. \frac{\gamma^4}{A^2.v^6} \text{ mol./litre,} \qquad (1)$$

where $\gamma = \frac{e^z - 1}{e^z + 1}$, and $z = \frac{\varepsilon.v.\psi_0}{k.T}$, $A = \pi^2.q^2.\lambda$.

The coagulating power of electrolytes is thus shown to depend on the electric potential on the surface of the colloidal particle (ψ_0), the valency of the coagulating ion (v), the absolute temperature (T), the number of atoms in 1 c.c. of the substance forming the colloidal particle (q), and the constant λ which appears in the equation $V = -\lambda/r^6$, giving the attractive potential due to the Van der Waals forces; ε is the electronic charge and k the Boltzmann constant. Although equation (1) is based on a rather crude physical model, namely, the interaction of plane electrical double layers, and although it has a limited range of applicability, being valid only if $d.\varkappa \gg 1$ ($1/\varkappa$ is the thickness of the ionic atmosphere and d is the mutual distance of the interacting colloidal particles), that is, for weak interaction of colloidal particles only, it nevertheless leads to a quantitative formulation of the Schultze–Hardy rule.

Wo. Ostwald[2] formulated a theory of coagulation of lyophobic sols which does not consider the mutual interaction of individual colloidal particles, but concentrates on the physical state of the dispersing medium, namely, the electrolytic solution of the coagulating ions. According to this theory, based on a careful study of experimental results, the stability of a given sol is influenced only by the 'activity coefficient' of the coagulating electrolyte. Independently of the type of electrolyte, the coagulation takes place at an approximately constant value of the activity coefficient of the coagulating ('dominant') ion. This theory, which seems to be just the opposite of the Verwey–Overbeek theory, may be formulated as follows:

$$f_0 \approx \text{constant,} \qquad (2)$$

where f_0 is the activity coefficient of the 'dominant' ion at which the coagulation takes place.

It may be of interest to direct attention to the close connexion existing between Ostwald's rule $f_0 \approx$ constant, and the results of the simplified Verwey–Overbeek theory, which according to my knowledge has not been noticed in the literature. In fact, it may be shown that Ostwald's rule follows directly from the Verwey–Overbeek theory.

For symmetrical (1–1, 2–2, etc.) electrolytes the Debye–Hückel theory gives the activity coefficient of an ionic species in water at 25° C. as

$$-\log f_0 = 0{\cdot}509 \sqrt{c.v^6}. \qquad (3)$$

Substitution of equation (1) in equation (3) gives

$$-\log f_0 = 1{\cdot}44\ \gamma^2/A.10^{11}. \qquad (4)$$

Since γ tends to unity even at moderate values of z, and A is a constant, equation (4) may be written as

$$-\log f_0 \approx \text{constant,} \qquad (5)$$

which is another form of the equation (2). Thus it is shown that, at least for symmetrical electrolytes, Ostwald's rule follows from Verwey–Overbeek's theory. The numerical value of the constant depends on the choice of the value for A. Unfortunately, Verwey–Overbeek's theory cannot give a value for A without taking into account experimental results concerning the coagulation values of electrolytes.

Inactivation of DDT by Soils

WE have read with interest the recent communication in *Nature* from H. Maes[1]. His report of the work of I. Vincke, who has observed a rapid loss of insecticidal power of DDT on the walls of certain African houses in the Belgian Congo, provides further evidence for the sorption of DDT on lateritic soils described by us in 1951[2]. It is also useful to find described a method for preventing this loss of efficiency; but we believe that the connexion between ability of soils to dehydrochlorinate DDT at elevated temperatures and loss of biological effectiveness is misinterpreted by Maes, and that the effect of spraying walls with phosphates is not due to inhibition of decomposition of DDT.

We have shown quite clearly that loss of effectiveness of surface deposits of DDT from wettable powders on certain soils is due to sorption of the DDT, and the presence of the undecomposed insecticide inside the soil structure can be demonstrated both colorimetrically and by recovery of crystalline DDT[3]. In addition, other insecticides, which are not susceptible to dehydrochlorination, disappear from the surface of soils in exactly the same way as DDT at rates which are approximately proportional to their vapour pressures. Possibly the sorbed DDT may be decomposed afterwards, particularly under dry conditions[3]; but the reaction is very slow at atmospheric temperatures compared with the sorption process and cannot account for the rapid loss of killing power against mosquitoes. However, as Downs *et al.*[4] have shown, there is a correlation between ability to dehydrochlorinate DDT in the Fleck and Haller method and the rate of loss of effectiveness on a wide range of soils, and therefore "the reaction of catalytic decomposition at 130° C. affords a rapid method for foretelling the capacity of a soil for inactivating DDT".

We would suggest the following possible reasons for the beneficial effect of pre-spraying mud walls with phosphate solutions. The correlation found by Downs *et al.* between the iron oxide contents of soils and the life of DDT residues on these soils would suggest that it is the iron oxide which provides the active sorbing surface. The phosphate ions may react with this surface to reduce its activity. Also, reaction with the ferric ions in the soil will produce gelatinous complex iron phosphates which may actually block the fine capillaries of the mud and retard diffusion of the insecticide vapours.

TECHNICAL AND TECHNOLOGICAL EDUCATION IN BRITAIN

IN a brief reference to the importance of encouraging technological education in his Messel Memorial Lecture to the Society of Chemical Industry last July, Sir Henry Tizard manifestly carried his audience with him when he expressed the wish for less talk about the necessity of restoring the balance of science and technology, and more action. It was then a month since Lord Woolton had made his statement in the House of Lords debate on science and industry regarding the Government's intention of "building up at least one institution of university rank devoted predominantly to the teaching and study of the various forms of technology", and it was on June 17 and June 19 that the Minister of Education had promised, in answers to questions in the House of Commons, that the Government's proposals for increased assistance for selected technical colleges and courses would be announced "in a few weeks".

A further three months have now passed, and in the meantime the latest returns from the University Grants Committee have disclosed no indication that under present conditions the proportion of students of technology in British universities and university colleges is increasing: an increase of 0·5 per cent in full-time advanced students of technology scarcely offsets a decrease of three per cent in the total number of full-time students of technology. Lord Woolton, on a previous occasion, had commented on Sir Henry Tizard's summons to a spirit of adventure in urging the fuller use of existing knowledge by British industry; and in referring to the widespread demand for a separate university of technology, he stressed the importance of technology in opening, at the Science Museum, the exhibition to mark the centenary of the birth of Sir William Ramsay. He said that much of the work of British scientific men has not been applied in Britain itself because of our failure to train and absorb into our industrial life the practical scientists we have come to call technologists. If, in the face of world competition through the application of the scientific discoveries of our time, we are to reap the national benefit that fundamental science offers us, it will be necessary to create in Britain technological universities with the status and the distinction that is given to our existing universities; and through them to train a race of people who will see that the successors of men such as Ramsay meet with the encouragement and the rewards that are proper for the services they render to the community.

It is known that Lord Woolton has been inquiring into the practical possibilities of giving effect to the Government's proposal. The choice in practice would seem to lie between building an entirely new university or expanding one or more existing institutions and giving them university status. The former course would involve a delay of five years or more before the new institution came into being, and another three or four years before it contributed to the supply of graduates. For the second course a choice would presumably be made between some of the existing major colleges of technology.

The Manchester College of Technology has submitted a strong case for making it one of the cardinal centres for supplying industry with the larger numbers of first-class technologists that are required. A statement from the governors, and approved by the Manchester Education Committee, shows that the College is already equipping itself to expand its work in higher technological education by strengthening what is already essentially the applied science department of the University of Manchester. The teaching staff is being reinforced by ten new chairs, and while extensions to the College will allow of more departments and more students, effect is also being given to long-cherished plans for decentralizing to new branch colleges much of the work below university-level.

The speed at which these plans can be executed obviously depends upon the readiness of the Ministry of Education to approve the capital expenditure involved, and the statement is worth noting as illustrating the way in which the expansion of technological education is interlocked with that of technical education, and the importance of framing policy so as to ensure that the expansion of both proceeds in step. No estimate appears to have been attempted of the desirable rate of increase in the number of technicians required by industry, although a recent paper on postgraduate activities in electrical engineering related this to the expansion of industry, and suggested that industry would require to increase its recruitment of staff from the universities and colleges by five to ten per cent per annum.

The inquiry into the relation between vocational and non-vocational studies in the education of technologists, which the National Institute of Adult Education is proposing to undertake, in co-operation with the Association of Technical Institutions and the Association of Principals of Technical Institutions, could well have some regard to the quantitative aspect also. Dr. P. F. R. Venables has pointed out that, while the inquiry particularly concerns the major technical colleges, any such investigation must extend far beyond these institutions. It has already been agreed to give the commission the most general terms of reference; and if, in fact, its inquiries extend to the training colleges of industry itself, and the residential colleges maintained by local authorities, as well as to the extra-mural departments of the universities and the educational activities of the research associations and professional institutions, it should have at its disposal much of the information required for a quantitative picture.

The statement regarding the Manchester College of Technology is also worth noting, because it indicates that, whatever choice may be made as to the college selected as nucleus for the new institution, assuming the idea of an entirely new university is rejected, the expansion of these major colleges of technology and of the existing university departments of technology is also essential. They have a vital contribution to make, not only while the new institution is being built up but also as a permanent element in higher technological education. The figures recently published by the University Grants Committee show clearly that so far as numbers of students are concerned, the expansion of existing university departments of technology could probably be pushed as far as Sir John Cockcroft has suggested without distorting the balance of studies. Whether, from the point of view of avoiding wasteful duplication of expensive equipment or those other considerations which Prof. A. R. Ubbelohde has stressed, it would be desirable to go quite so far is another question.

It does not appear, however, why there need be much delay in making the necessary preliminary decisions, such as the location of the new institution and the approximate scale on which it is to be planned. Without prejudice to the merits of the case for the Manchester College of Technology—and the arguments for making it the nucleus of the new university of technology are by no means as convincing as those for the expansion at present projected by the governors, largely because of doubts as to the existence of sufficient room for expansion on the university scale—Manchester had every reason to expect some further statement from the Government when Lord Cherwell and Miss Horsbrugh received the honorary associateship of the College at the commencement of its jubilee celebrations on October 11 Lord Cherwell, in Lord Woolton's absence through illness, said nothing further about the Government's plans for higher technological education, either in relation to the Manchester College of Technology or regarding the new institution. Miss Horsbrugh quite properly disclaimed any responsibilities for highe technological education, but maintained her silenc as to the plans for technical education, which is stil a responsibility of her Ministry. Whether or not th occasion was appropriate for a general statement o technical education, the delay has now far outru any reasonable interpretation of the "few weeks claimed by the Minister in June.

That delay must in itself affect the execution o the plans for the expansion of the Manchester Colleg of Technology. These plans, as already noted, contemplate the decentralization to subordinate centr of some of the more elementary work. Colleges technology cannot give full scope to the mo advanced work, and particularly postgraduate studi and technological research, the importance of whi has rightly been stressed so strongly in the curre debate on technological education, if they are at th same time to house elementary technical studies. may not, indeed, be a wise step, either at Manchest or elsewhere, to divorce the colleges of technolog entirely from work of a non-university standa although if provision is made for part-time studen from industry, the drawbacks of making such colleg exclusively university bodies should be minimized.

To establish satisfactory relations between high technological education and the industrial world i vital matter ; much must depend on the co-operati of industry. One of the assets of existing institutio like the Royal Technical College, Glasgow, Imperial College of Science and Technology, Lond and the Manchester College of Technology is that th have already established links which should be p erved and are indeed capable of extension. There , however, a quantitative aspect also, and it is his that shows up the weakness of the present rrangements for technological and technical educaion in Great Britain.

The colleges of technology cannot divest themelves of their present responsibilities for technical ducation, until alternative arrangements have been nade for the education elsewhere of the technicians nd craftsmen required in even greater numbers than echnologists, and whose supply must expand in roportion as that of the technologists increases. 'hese arrangements remain, however, the responsbility of the Minister of Education; and although hat Minister will cease to be responsible for such of he colleges of technology as are given the academic reedom generally agreed as essential in higher techological education, it has not yet been made clear vhere the responsibility for the latter is to rest.

Meanwhile, the unsatisfactory nature of the resent position and the desirability of placing the esponsibility for the general supervision of higher echnological education unambiguously on the same ody that is responsible for watching over the niversities is emphasized by such piecemeal action s that at Loughborough College. While the Minister f Education dallies in announcing a general policy, he has relieved the Leicester Education Authority of esponsibility for maintaining the engineering and cience departments of Loughborough. These lepartments will now be organized as a separate stablishment, to be known as the Institute of Technology, Loughborough College, maintained rincipally by a grant from the Exchequer. The Minister has set up a governing body which became esponsible for the Institute as from September 1; ut it is not clear whether the new institute will have the academic freedom of a university institution r whether it is primarily a technical rather than a echnological institute. What is manifest is that the levelopment should have followed, rather than receded, the Minister's statement as to general olicy. The development will not diminish the videspread concern that both in technological and in echnical education Government aid will be spread oo thinly over too many institutions. When esources are limited, it is imperative that they should e distributed in accordance with a clearly and careully thought-out policy, and not in response to articular representations.

It is impossible, therefore, to regard Miss Horsrugh's remarks on October 11 with any satisfaction. A clear statement of policy is long overdue, and vague ssurances of doing her best to meet the needs of oth university and non-university work at Manhester and to help the Manchester Education Authority with its plans to build new local colleges re not enough. Some clear thinking is also required s to how and where to meet the needs of the partime students to which Mr. David Cardwell, acting rincipal of the Manchester College of Technology, eferred. Particularly at the present time, such tudents offer a promising means of securing that ubstantial increase in the number of graduates in technology which is so urgently required. Whether this could contribute towards an increase in post-graduate students and research workers in technology may require examination. Much would depend on the co-operation of industry; but so far as the remedying of Britain's weakness in the pursuit of technological research in academic institutions is concerned, Mr. Cardwell possibly put his finger on the real weakness in referring to the need for research grants. These clearly should not be expected to come from the local authorities, and if they are to come from the Exchequer, there is the more reason for giving the technological institutions concerned the independence and academic freedom necessary for the prosecution of research under the guidance of staff of the right calibre.

No one would suggest that, once the Government has made clear its plans for the expansion of both technological and technical education, the execution of those plans can be anything but a slow process. The concentration of technological education in a relatively few institutions, and the divesting by those institutions of their responsibilities for technical education, are bound to be gradual and may be protracted. The upgrading of the selected technical colleges in itself requires time. As an article "Education for a Scientific Age" in *The Round Table* recently observed, in this connexion, status and prestige cannot really be given: they must be won. It is likely to take some time before the degrees and diplomas granted by the upgraded colleges will be recognized as of the same value as those of a university.

Progress clearly depends largely on the calibre of the staff that the technical colleges are able to attract; they must be able to offer the conditions of academic freedom and salary that characterize a university institution, and this is one reason why early decision is imperative. Until policy is announced, the formulation of plans cannot proceed, and waste and frustration are likely to persist, to the detriment of that large measure of agreement which has already been reached as to the lines on which technological education should develop. Even the expansion of the university departments on the lines suggested by Sir John Cockcroft is likely to be hindered until the University Grants Committee has received such guidance from the Government.

Indecision in this matter, moreover, is a great handicap to the task of educating public opinion, which was so strongly urged in the last report from the Advisory Committee on Scientific Policy. Decision on the part of the Government is the first essential; given that, there is no reason for anticipating further delay on the part of the institutions concerned in giving effect to the policy formulated. It is to be hoped that in both Houses of Parliament early opportunity will be taken to press the Government on the matter, and that the pressure will be maintained until a decision is announced. On the Government's own showing, the whole question is too important to the future of Britain to be allowed to remain indefinitely in the position when a change of Government could once again throw the whole matter into the melting-pot.

PROGRESS IN COSMOLOGY

Cosmology

By H. Bondi. (Cambridge Monographs on Physics.) Pp. ix+179. (Cambridge: At the University Press, 1952.) 22*s.* 6*d.* net.

IN his presidential address to Section A (Mathematics and Physics) of the British Association in 1888, G. F. FitzGerald suggested that "a successor in this chair might well devote himself to a review of the cosmical theories propounded within the last few years". He added, "The opportunities for piquant criticism would be splendid". Since there seems never to be lacking a supply of these theories produced "within the last few years", there is naturally not lacking a number of men of science still sharing FitzGerald's attitude towards them.

Criticism there must, of course, be. But the important thing is that general progress is being made in the study of the large-scale problems of the physical universe. Observational evidence is accumulating; this in itself is almost inevitable, but there is also progress in appreciating its relevance and significance from a general physical point of view apart from highly specific theories. On the side of the theories themselves, much has been learned that could be discovered only by the actual working out of the results of their attempted application to the cosmological problem; each serious new theory seeks to overcome the difficulties encountered by its predecessors. In the course of the work, much has been learned, too, about various general physical theories as such, apart from this particular application. Some theorists would claim that fundamental insight has been gained into the origin of laws of Nature. Above all, the main problems to be solved in cosmology are becoming more and more clearly formulated; and, though the theories differ greatly in their ways of getting results, when due regard is paid to the features common to the results themselves, definite progress towards the solution of some of these problems can undoubtedly be claimed.

As a masterly account of this whole state of affairs, it is hard to imagine anything that could be better than Mr. H. Bondi's book. By the exercise of the greatest skill in marshalling his material and of the utmost clarity of expression, he succeeds in making his account effectively complete without any sense of undue compression. Also, he does not shirk the exposition of what is essential in the technicality of the work, while always giving primary attention to the concepts involved.

Though scrupulously fair to other theories, Mr. Bondi naturally states his preference for the "steady-state" theory of cosmology, with its concomitant hypothesis of the continual creation of matter. This theory was originated by him and T. Gold in 1948. They did not claim that it *must* be correct, but Mr. Bondi points out the extreme epistemological difficulty in the way of any fundamental progress if it is found to be false. Actually, it does seem to give a better account of the large-scale behaviour of the universe than does any previous theory. However, it encounters the obvious trouble that the universe does not conform strictly to the "perfect cosmological principle", from which the theory is derived, though there is no evidence that it does not conform statistically. F. Hoyle's alternative approach, originally published about the same time, is more satisfactory from this point of view, but Hoyle was not so concerned to deal with the epistemological situation. All this is clearly explained in the book.

It seems to me that the relationship between the procedures of Bondi and Gold and of Hoyle indicates the way in which further progress may be expected. They illustrate the "deductive" and "extrapolating" procedures so well distinguished by Mr. Bondi (p. 5). Whereas in the past this distinction has been ill-recognized and has resulted in fruitless controversy, we now have an instance of the procedures tending to consistency. A fundamental examination of the conditions for consistency of the two types of procedure is required and may yield the next advance.

W. H. McCREA

AMPHIBIANS OF WESTERN NORTH AMERICA

Amphibians of Western North America

By Robert C. Stebbins. Pp. xvii+539 (64 plates). (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1951.) 56*s.* 6*d.* net.

IT is refreshing to find an author who makes no pretensions to writing for the benefit of some section of his fellow men, but says with simplicity, "I have put into the volume what I have wanted to know . . .". The result reveals Mr. R. C. Stebbins as a naturalist, and for anyone who, like him, wants to know not only what amphibians occur in western North America but also, and above all, how and under what conditions they live, the book provides a great many answers; it also provides a wealth of comparative information for others of similar bent but concerned more directly with other geographical regions.

As a member of the staff of the Museum of Vertebrate Zoology of the University of California, the author is an experienced taxonomist, and the framework of the book is the taxonomic arrangement of the animals. There are keys, accompanied by explanatory diagrams, for the identification of the animals both as adults and larvæ. Species and subspecies are described and figured, and their general and local distribution indicated and mapped. Then, for each form, there are extensive notes on its behaviour, habitat, food, reproduction and so forth. These notes are based on the author's personal observations or are taken from impeccable sources, many of them hitherto unpublished. Twelve plates show typical habitats, and there is a glossary of technical terms as well as an index.

No book of this kind can satisfy everybody. Those whose interests are mainly ecological will doubtless regret the absence of physical data relating to the different types of habitat, information regarding predators, parasites and so on. Others, more taxonomically inclined, will wish that more had been said about the very interesting phenomenon shown by the salamander *Ensatina eschscholtzi*, where the end-terms of two subspecies chains, deriving from a common stem, meet and behave as distinct species; that more, too, had been said about the discontinuous distribution of *Ambystoma tigrinum* and its causes, and that genera and subgenera had been less capriciously treated. But apart from such matters of scope and emphasis, there are few serious defects for criticism. The segregation of the illustrations of the larvæ and of the distributional maps away from the main accounts of the species has the advantage of facilitating direct comparisons but little else to recommend it. Some may also find it a nuisance that habitats are sometimes described in terms of life-zone concepts (for example, Sonoran, Hudsonian, Arctic Alpine) that are not defined in the book, rather than in terms of the natural vegetation the distribution of which is mapped (Plate 47).

There can be no doubt of the quality of this book with its reliable information and excellent illustrations, and equally there can be no doubt that its publication will stimulate studies that must result in an increased knowledge of a group of animals still relatively little known. H. W. Parker

SCIENTIFIC PRINCIPLES OF FURNACE TECHNOLOGY

The Science of Flames and Furnaces

By M. W. Thring. Pp. xiv+416. (London: Chapman and Hall, Ltd., 1952.) 42*s*. net.

THIS book is a useful contribution to the scientific study of flames and furnaces, a subject in which a fairly extensive background of applied science already exists, but is not readily accessible to the average reader of the subject. Furnace design is a somewhat specialized subject, and furnace practice is almost every industrialist's concern. Nevertheless, the systematic treatment of the subject in text-books has been curiously enough neglected. It would be unfair, however, to claim that furnace technology is therefore backward, though frequently such criticism of modern furnace development has been heard. In point of fact it is commonly the rule in the technology concerned with the development of valuable industrial plant that practice is in front of the text-book exposition of the subject. In the present case, however, as the title of the volume indicates, the author is concerned with the science rather than with the technology of the subject.

The introductory chapters are devoted to the heat liberation from the flame and the subject of heat transmission. Novel features deal with the interpretation of the second law of thermodynamics in terms of what has been called the 'virtue' of a system's energy, and a more than usually complete treatment of the subject of flame radiation. One doubts whether the introduction is necessary of such special terms to define the obvious value of the heat potential of the fluid above the levels of temperature in the furnace. Indeed, such may even lead to confusion of ideas. Useful summaries of recent experimental work in furnace investigations, in heat transmission and in the determination of thermal constants are given. These constitute perhaps the most valuable features of the work. Again, under the somewhat pedantic title of "Aerodynamics of Hot Systems" are included those sections of the work which describe the science of draughting of furnaces and of jets of hot gas. This chapter comprises a good collection of references, but resembles so much a series of notes and mathematical formulæ, signs of a worthy effort to collect as much information as practicable into a limited number of pages, that the reader is left with the feeling that for an effective understanding of the subject he must still consult the original papers. The chapter purporting to cover the science of furnace construction is mainly devoted to refractory and insulating materials. It is so condensed that it serves only to give guidance to a very limited series of references.

The final chapter on scientific method is a valuable and suggestive one.

The paragraphs are numbered in the manner of the Cambridge mathematical texts. It is doubtful if the average reader takes much notice of the numbering, but he will profit from the useful summaries at the ends of the chapters. This may in some degree compensate for a somewhat meagre index. The book is well produced, the printing clear, and the illustrations legible.

ORNITHOLOGY OF THE CHANNEL ISLES

The Birds of the Channel Islands

By Roderick Dobson. Pp. xvi+263+25 plates. (London and New York: Staples Press, Ltd., 1952.) 30*s*. net.

IN the middle of the last century a great change began to take place in the use of the land in the Channel Islands, owing to the development of early fruit and vegetable growing for the London market. This necessitated the cutting down of orchards to make room for glass-houses, the draining of wet ground, and clearing of rough areas for early potatoes. Unfortunately there is little information as to the status of the resident species, or summer visitors, previous to 1866 when Cecil Smith published his "List of Birds . . . Summer Visit to the Channel Islands, exclusive of Jersey", which was amplified in his "Birds of Guernsey" (1879). Some species have ceased to breed owing to the increased utilization of the land, and others from some unknown cause. The choughs, for example, were common in Guernsey in 1878, in Alderney they ceased to breed in 1876, in Jersey in 1880, and in 1929 a pair were seen in Guernsey—the last record for the Channel Islands. In the British Isles the increase of jackdaws is sometimes blamed for the decrease of the chough; but in the Channel Islands jackdaws were never very abundant and have now decreased, and only a few nest in the western half of Jersey.

It is interesting to note that during the German occupation carrion crows, which in the breeding season were formerly confined to the cliffs, began to nest in woods and trees inland. This was owing to all the farmers' guns having been confiscated. During the same period the Germans felled many of the tall trees in the sheltered valleys, with the result that in a year or two the undergrowth increased and blackcaps and garden-warblers began to nest again, which they had not done for many years. On the cliffs and rocky islands around Guernsey and the other main islands, many kinds of sea-birds breed and, during the Second World War, an additional species--the gannet—established colonies on the rock of Ortac and Les Etacs, off Alderney.

The information about each species is arranged in this book under the four largest islands, and in some cases the available information is rather meagre; nevertheless this is a valuable contribution to the ornis of the Channel Islands, and no doubt in a future edition there will be many additions to the list of species, especially among the migrants. There are a number of photographs of various birds, nests and well-known breeding places.

UNIVERSITY BOTANICAL TEACHING AND TRAINING

IN *Nature* of April 28, 1951, the leading article raised the importance of university departments of biology (both botany and zoology) for the training of biologists to satisfy the needs of the modern State. We then pointed out that among those working in the wide and varied field of applied biology there was a general conviction that Great Britain and the Commonwealth was suffering from a dearth of plant and animal physiologists. This article inspired Sir William Slater to write shortly afterwards (*Nature* of June 2, 1951) to point out that the Agricultural Research Council was seriously concerned about the shortage of animal and plant physiologists with an adequate knowledge of chemistry and physics and of biochemists with biological experience, and to emphasize the important efforts which the Council was making in this direction.

This adds point, therefore, to the discussion organized by Section K (Botany) of the British Association on September 5 at Belfast. The discussion is fully reported in the following columns by Prof. L. J. Audus. The three main contributors to the discussion—Dr. Eric Ashby, Dr. W. B. Turrill and Mr. Peter Bell—raised issues of the utmost importance. We felt, however, that this was a very important discussion, and that it, like most discussions in connexion with which no special invitations to speak had been accorded to anyone other than the readers of the main papers, might prove to be an unbalanced review of authoritative opinion throughout the country, in spite of the fact that a number of botanists contributed useful points after the papers had been read.

So it was decided to approach a number of other botanists who either were not present at the discussion, or, if they were, did not speak, to contribute their views now. Copies of Prof. Audus's report were sent to them and their comments follow the main report here. In most cases, no department of botany was approached if one of its members had spoken at the Belfast meeting. It should be pointed out, however, that Prof. Audus himself was invited to submit a written comment, since, with the aim of making his written report as objective as possible, he did not speak at the discussion itself. A few authorities, for specific reasons, preferred not to contribute to this discussion.

Although in most cases the head of the department was originally approached, and in some cases it seems that he consulted his assistants, it should not be taken for granted that any one contribution is the considered opinion of the entire department concerned.

It will be noted, as one might expect, that the opinions expressed indicate that the problem is heterogeneous; for example, the small department has problems which the large department does not have to face. Moreover, individual authorities raise special points. But apart from this, there are several general themes which have been brought out, and these might with advantage be given careful consideration by all university and college departments of botany.

The British Association Discussion

THE rapid expansion of botany as a university subject in recent years and its growing importance in a world faced with grave food shortages has recently caused university staffs to reconsider whether present degree courses are suited to modern needs. A whole morning's session in Section K (Botany) of the British Association was devoted to "The University Training of a Botanist" at the Belfast meeting on September 5.

DR. ERIC ASHBY (QUEEN'S UNIVERSITY, BELFAST), who opened the discussion, explained that the purpose of his paper was to examine the botanical curriculum, its determining factors and the case for its reform. To keep the discussion within bounds it was necessary to limit its scope to honours courses in botany considered solely as a training for professional botanists (not including school teachers).

The curriculum should be influenced by: (1) the corpus of botanical knowledge and fields of current research; (2) the requirements of employers; (3) the aptitudes of students. Other 'illegitimate' influences, for example, the bias of university staff and inertia of examiners, would be disregarded.

(1) The corpus of botanical knowledge has changed enormously since 1900. From 1900 until 1910 it was sufficient only to know botany in order to understand any botanical research paper. From 1940 until 1950 many papers could not be understood without some knowledge of chemistry, mathematics and physics. The change was illustrated by a study of examination papers over the past fifty years. Thus the examinee of 1950 was expected to answer some 95 per cent of questions set forty to fifty years ago, whereas an examinee of 1900–10 could not have attempted some 40 per cent of the 1950 questions. By and large, honours botany curricula still contain as much comparative morphology, etc., as they did in 1910, while genetics, much more physiology, ecology and cytology have all been squeezed in without any lengthening of the course.

At the research-level the classical problems are still relevant and no nearer solution than they were fifty years ago, and we would do a serious disservice to our subject if we discarded those problems or no longer taught the raw materials necessary for thinking about them. Meanwhile most botany research workers prefer fields where solutions are easier to obtain, as is shown by the type of research taken up by British postgraduate botany students in 1951 (University Grants Committee data), that is, taxonomy 8; genetics 30; ecology 16; physiology 22; pathology 16; mycology 14. Thus the content of botany has enormously enlarged, yet the material included fifty years ago cannot be entirely discarded. This is the dilemma of the botanical curriculum.

(2) Universities are primarily institutions for training professional men and women. In 1900 most botanists were employed by universities, herbaria and botanical gardens. To-day there is a much wider range of employers. Apart from the teaching profession, the biggest employer of botanists is the Government (Agricultural Research Council and

Department of Scientific and Industrial Research), then the Colonial Service and then the universities. Demands are for physiologists, biochemists, pathologists, plant breeders and experimental ecologists. In 1950 the Ministry of Labour and National Service published a pamphlet stating that over the period 1950–54 the supply of honours botanists was likely to be about twice the demand. Although these demands were probably underestimated, yet even with adjustments the figures are disturbing. Notwithstanding this threatened excess, bodies like the Agricultural Research Council and the Colonial Office cannot get recruits of the right calibre or training for their vacancies [see also *Nature*, 167, 659 and 908; 1951]. The majority of honours botanists that apply can discuss at length the classical problems of morphology but cannot, for example, design the simplest field experiment in agricultural botany. They are therefore of no use to these principal employers.

(3) The aptitudes of botanical students have changed in the last fifty years. On the whole, in 1900, botanical students were naturalists. They had, therefore, good visual memories and enjoyed the techniques of evaluation as contrasted with measurement. But most modern botany students are fundamentally not naturalists. By temperament and aptitude they are experimentalists. For them field-work is difficult, and they must learn their plants anew each year. They are uninterested in the arguments of classical botanists. These two kinds of student are as different as chalk is from cheese yet we are forcing them both into the same mould. The born taxonomist ploughs his way in misery through the tortuous paths of metabolism. The born physiologist suffers resignedly the unconvincing arguments of the morphologists. It is our duty to change the curriculum to meet the needs of both these types of botanist.

The conventional adjustment of the curriculum is usually to reduce the number of types, to skimp reading of classical papers, to cut practicals but never to leave even one group out. As a guide in making reforms, however, one should take as a model the techniques of the classics curriculum. There seem to be two principles involved. The first is to select a few authors and to study them exhaustively until one lives in the climate of their thought; the second is to ensure complete familiarity with comparatively few works of genius. The power of classical education depends on this second principle. This contrasts strongly with the principles underlying an honours course in botany. Here insistence on some contact with every aspect of the subject inevitably means that only the most superficial consideration can be given to any one subject and nothing can be studied exhaustively and really understood. On the experimental side this is particularly marked, and is positively harmful, for it misses the main point of experimental work, that it is not always successful and that the experimenter has to repeat and repeat until results are consistent. Furthermore, one can graduate well in botany without ever having opened a book by Darwin or read a paper by Sachs or F. F. Blackman, but not if one has omitted to struggle through a score of books by industrious but negligible writers just because they contain the most recent information.

Dr. Ashby next turned to some practical proposals He first assumed that it is not possible on economic grounds to lengthen the honours botany course. This means that something must be omitted. The first omission should be compulsory zoology. Although it might be desirable for school teaching and certain very specialized jobs, the professional botanist has far more to learn from the chemist, the mathematician and the physicist. In the first post-intermediate year let all botanists do the same general course. The non-experimental botanist, who is easily distinguishable even at this stage, should take in addition geology and some zoology, while the experimental botanists should take instead chemistry and physics. In the second and third post-intermediate years they should be separated into two streams. The non-experimentalists would take anatomy, comparative morphology and evolution, taxonomy, floristic plant geography, genetics; together with geology, some zoology and some climatology. The experimental botanist would take anatomy, physiology, experimental ecology, genetics, plant pathology, mycology; together with chemistry, biochemistry, physics (properties of matter and some physical techniques), elementary mathematics and statistics. This would leave time for work to be done with a precision and thoroughness not devoted to it for forty years. It would, indeed, turn out botanists who had never 'done' the vascular cryptogams except in an elementary course and others who would not be able to read a modern paper on photosynthesis; but it would produce a taxonomist who has spent time on palæontology instead of wasting it on fat metabolism and a physiologist who knew enough physical chemistry to understand fully modern papers on salt absorption, etc.

DR. W. B. TURRILL (THE HERBARIUM, ROYAL BOTANIC GARDENS, KEW), who followed, confined his attention to the teaching of angiosperm systematics. He was tempted to suggest that taxonomy could not be taught. What can be done is to train the student to teach himself However, the attempts that had been and still were being made to do so could be classified under six heads.

(1) The direct method of selected 'type' families, which is extremely dull.

(2) The historical method, which is wasteful of time as a basis for modern teaching.

(3) Philosophical method. This could be properly effected only with students already possessing considerable experience.

(4) Phylogenetic method. This is the easiest method to teach; but the dangers are that speculations would be taken for established fact.

(5) Practical. Here there are several different approaches; but in all it is essential that the student shall handle material himself and learn to work out characters, constancies and correlations from specimens and not from lecture notes. Advantages are that learning is easy, initiative is at a premium and the research habit is developed.

(6) Synthetic method. This is the method for the future whereby all the good points under the preceding five headings are combined and the bad ones are eliminated. How far is this synthesis possible?

There are clearly two types of botanist, taxonomist and non-taxonomist; but the latter should have a sufficiently wide knowledge of taxonomy to be able properly to appreciate its purpose, methods and problems. Taxonomy cannot be learnt by the 'type' method. Its very essence is the detection of correlations. Selection of material is essential; but too early specialization must be avoided. Early on, the need for a universally recognized system should be simply explained and theories concerning it briefly outlined. Students should then be turned loose in the field with a flora to work out the plants of an area for themselves. Later there should be concentration on a few families limited to the local flora: not as 'types' but for the study of character evaluations, correlations, variation and reticulation. Then there should follow the study of a single genus in detail, perhaps extended to extra-British species.

Since the British flora is too limited to furnish a full appreciation of variation of structure and behaviour, serious study should eventually be made of at least one tropical family.

Detailed theories of classification should be deferred until the student has acquired sufficient facts to appreciate the linkage of practice and theory; but suggestive generalizations should be introduced gradually as factual knowledge grows, and to this end modern methods and detail should replace historical subjects. An experimental garden is essential, since in it students can learn much of fundamental importance, such as distinctions between phenotype and genotype, character plasticity, genetic isolation, etc. The study there of species problems will lead to integration of orthodox taxonomy not only with morphology but also with all that is latest in plant physiology.

The number of posts for professional taxonomists is limited. Only those students who have a definite flair for it should be encouraged to take it up as a career. Only a few universities are at present equipped to give the necessary specialized training. Other university departments of botany should aim at giving their students a sound general training, as already outlined, and leave specialized training to a postgraduate apprenticeship period at some centre of taxonomic research.

MR. PETER BELL (UNIVERSITY COLLEGE, LONDON) regretted the omission from Dr. Ashby's paper of aspects of training bearing on the teaching of botany in schools, since most present-day students came up lamentably equipped for a modern course in botany. The analysis of subjects chosen for research by recent graduates was of no significance in the discussion, since such choice was dictated primarily by the availability of money for specific subjects.

He could not agree with Dr. Ashby that the specific requirements of government departments for special types of botanist should be allowed to influence the content of an honours degree course. He did, however, agree with his two principles of teaching, that is, doing a few things well and becoming familiar with the workings of powerful intellects. This first principle was frequently adopted in morphological teaching. The difficulty of dealing with the second would be to decide who were the great minds in the botanical world.

Turning to Dr. Ashby's concrete suggestions for reform, he held that students could not be divided readily into "naturalists" and "experimentalists". There was a complete dovetailing of both these aspects over the whole field of botany. Up to graduation the botanist's training should therefore be general, and special accessory knowledge for experimental research, for example, statistical methods, physical chemistry, etc., should be picked up when the need arose in postgraduate years. A general view of the advances in the whole subject was essential for anyone attempting research in botany.

In the informal discussion which followed, most of the speakers agreed that Dr. Ashby's suggested reform required specialization at much too early a stage, before students could be reasonably expected to have decided precisely what aspect of botany they wished to follow.

DR. H. HAMSHAW THOMAS (CAMBRIDGE) said that botany courses could and should provide a real intellectual training for students, by no means all of whom were destined to become professional botanists. This should include the writing of clear and intelligent English and an appreciation of the meaning and implications of words. He hoped that Dr. Ashby's suggestion that we might profitably copy the excellent teaching methods of the classicists would be given careful attention.

PROF. JOHN WALTON (UNIVERSITY OF GLASGOW) said that the training of research workers in a special line should be left to the Ph.D. period, when they should take courses in those allied subjects that they specially required, for example, biochemistry, statistics, genetics, etc.

DR. JOHN RAMSBOTTOM (FORMERLY BRITISH MUSEUM (NATURAL HISTORY)) pointed out that botanical courses were designed originally for teaching botany as a discipline, almost entirely to intending teachers, and were correspondingly stereotyped. This tradition persisted. Before steps were taken, however, to make it difficult to study botany as a whole, an effort should be made to produce a more balanced and realistic syllabus.

DR. J. L. CROSBY (UNIVERSITY OF DURHAM) said that the history of botany should be an important part of any university course in order to understand how ideas have developed and to obtain full benefit from the botanical classics.

DR. J. HESLOP HARRISON (UNIVERSITY COLLEGE, LONDON) found it difficult to accept Dr. Ashby's proposition that botanical science could be divided into experimental and non-experimental. If those botanists who are to tackle the unsolved classical problems are to be segregated early from the physiologist stream, then this is the way to ensure that those problems are never solved. Little can now be expected from purely observational methods, and the past forty years have shown us that progress with these problems can best be achieved by application of experimental techniques by those trained in physiology. Specialization must therefore be deferred at least until the student has gained some appreciation of the science as a whole, which is usually not until he has graduated after a broad general honours course.

DR. P. F. WAREING (UNIVERSITY OF MANCHESTER) suggested that 'botanists' did not appreciate the real point at issue. The modern plant physiologist requires a knowledge of very advanced chemistry and this cannot be 'picked up' when needed after graduating. Dr. Ashby's scheme was to meet this difficulty, and so far no other practical alternative had been suggested.

The student point of view was put by MR. J. E. DALE (KING'S COLLEGE, LONDON), who said that the good student would plan his own course of study, irrespective of academic direction. He is the person who ultimately decides where and when specialization will start.

DR. W. MATHIAS (UNIVERSITY OF LIVERPOOL) was sympathetic with the view expressed by Dr. Hamshaw Thomas that a university training should be non-vocational, but how many present-day students are stimulated by considerations other than vocational?

Dr. Ashby replied to the points made during the discussion. He said that the chief objection raised against his suggestions was that they involved specialization at too early a stage in the botanical course. But the honours student is committed to early specialization in any event; and it was therefore necessary to weigh its drawbacks against the advantages of a thorough training. L. J. AUDUS

Further Contributions

PROF. L. J. AUDUS, BEDFORD COLLEGE, UNIVERSITY OF LONDON

The modern professional botanist, whatever his particular specializations, must possess a proper appreciation of modern concepts on form and function in the plant kingdom. For this he needs, in addition to his general botanical training, a thorough grounding in chemistry, physics and mathematics and a knowledge of certain aspects of these subjects as deep as that possessed by the relevant specialist. In addition, the experimental botanist entering Government or Colonial Service needs a knowledge of special techniques that can be neither quickly nor easily acquired. It is altogether too optimistic to suggest that all this can be squeezed into a three-year honours course, even with the modifications and omissions proposed by Dr. Ashby.

A fourth postgraduate year for specialized training is essential if we are to avoid turning out mere 'technicians' as a result of too early and too narrow a specialization. The courses in the three pre-graduate years need not differ in structure from those at present in operation except that physics and chemistry of an appropriate type and standard should be obligate subsidiary subjects. Specialization in botany should not be carried quite as far as it now is in some honours schools, but extra time should be devoted to particular associated techniques, for example, statistics, etc. In the postgraduate year the specialization could be as extreme as the particular types of training demand and could terminate in an M.Sc. by examination. The school teacher would, as now, follow the course up to the first-degree stage, and this would avoid the invidious distinctions, implicit in Dr. Ashby's suggestions, between professional botanists and school teachers, whose prestige has already fallen dangerously low. We must nurture our prospective teacher on the same interesting diet as we nurture our prospective research workers or we destroy at the source the interest and enthusiasm of our future professional botanists.

PROF. T. A. BENNET-CLARK, F.R.S., KING'S COLLEGE, UNIVERSITY OF LONDON

IT was evidently suggested by many speakers that Dr. Ashby's proposed reforms required specialization at too early a stage, and the astounding view was even expressed that "physical chemistry, etc., could be picked up" after graduation. Incidentally, why not pick up extra morphology after, rather than before, graduation?

All this reads like the most unwelcome proposition that pure botany is more desirable academically than a broadly based scientific training with appropriate chemical, physical and biological disciplines. To regard this pure botany as less specialized than Dr. Ashby's experimental course is incomprehensible.

The narrow specialization of the botany of fifty to sixty years ago represents a very arbitrary segregation of a single compartment of natural knowledge largely determined by the direction of research in the eighteenth and early nineteenth centuries. It is no longer a very convenient subdivision, if students are to be forced by syllabuses or regulations to remain confined within it, when current research advance is in the so-called borderline sciences. My support for reform on lines like those suggested by Dr. Ashby is based on the belief that such reform could permit less specialization than frequently occurs now and that it should also blur the very arbitrary sharp boundaries between the sciences. Different universities would no doubt attempt different patterns of reform to permit easy integration of the basic sciences.

PROF. G. E. BRIGGS, F.R.S., UNIVERSITY OF CAMBRIDGE

The system of training botanists which Dr. Ashby criticizes and that which would result if his amendments were adopted are different from that which has developed at Cambridge. As it has been intentionally adjusted from time to time as the subject has developed, it may be useful to others to describe its present state.

During his first two years a student must read at least two other sciences chosen from a wide range, including mathematics, the only restriction being that of the time-table. For example, he can combine chemistry, physics and mathematics with his botany or he may read zoology and geology. A common combination is botany and zoology with organic chemistry and biochemistry, the two latter together counting as one subject. In his third year, when he reads only botany, he is encouraged to attend lectures and practicals in all branches; but the examination allows for specialization.

The bias of the university staff is allowed to have an influence. No attempt is made to cover the whole field of botany, nor do we try to deal with all the sub-sections of a section such as plant physiology. By dealing with the parts of which he has special knowledge, the lecturer hopes to form habits in the student which will be generally useful to him at a later stage.

PROF. A. R. CLAPHAM, UNIVERSITY OF SHEFFIELD

Dr. Ashby is surely incorrect in saying that "by and large, the honours botany curricula contain as much comparative morphology, etc., as they did in 1910": there are several university departments in which only one or two selected groups are treated in the old detail, the time so saved being devoted to modern branches of botany, experimental or non-experimental. I agree with him that honours courses should not be lengthened; but I agree with Dr. Peter Bell and others that there should be no division of the undergraduate class into 'naturalists' and 'experimentalists'. Students cannot be clearly divided into such categories, and they should not be obliged to make the implied decision before they take their first degree. I have known many whose primary interests were taxonomic or ecological but who were either experimentalists by inclination or who at least recognized the desirability of a training in experimental attitudes and techniques. Such men ensure that no branch of botany remains non-experimental, and they contribute in a most valuable way to botanical progress.

It is, moreover, undesirable that there should be any lessening of the opportunities for contact between honours students of diverse interests, for this contact plays an important part in undergraduate training. The experience of many botanical departments is that it is not difficult, by the careful designing of courses and examinations, to continue to give a wide botanical training and yet to foster special interests to an adequate extent. If these courses remain at their present length there is time for narrower specialization in postgraduate courses of training in research.

Prof. Ronald Good, University College, Hull

Many will agree with Dr. Ashby's diagnosis that the problem now facing teachers of botany in universities is due partly to the growth in content of that subject and partly to a tendency for it to become increasingly vocational, though how far the former reflects the latter may be more debatable. It is often suggested that some reduction of the burden by a process of sub-division or dichotomy has become inevitable, and it is therefore important to remember that there is more than one way in which this might be achieved. That most commonly mentioned is by division on the basis of subject-matter, which may be called the 'physiology or morphology' point of view, but there is also the possibility of making the division more clearly one between the academic and the technical.

The real trouble is that at present the fiction that the whole subject of botany can still be taught in a single manner for all purposes results in too frequent failure to do the thing which matters most, namely, to provide, in Dr. Hamshaw Thomas's phrase, "a real intellectual training for students". Might not the inevitable dichotomy be better made between students rather than between parts of their subject, so that the training of those with greater natural scientific aptitude might be different from, and perhaps more academic than, that given to those whose gifts lie more in the application of knowledge ? If this is indeed the direction in which a solution of the problem is to be found, however, then one cannot but wonder how long a design of higher education which contains only one pattern of university institution and but a single system of degrees will continue to be entirely sufficient.

Prof. F. G. Gregory, F.R.S., Imperial College of Science and Technology, London

In recent years botany has developed rapidly as an applied science: in (*a*) pathology, (*b*) plant breeding, (*c*) agronomy or crop physiology. Meanwhile botany remains as before a pure science embracing anatomy, morphology, systematy and physiology. The curriculum should be adjusted to both these needs. It will inevitably be influenced by the interests and capabilities of the teaching staff.

Dr. Ashby's suggestions for the reform of the curriculum seem acceptable and indeed are urgent. There are two types of botanical students, and after the preliminary post-intermediate first year both types should be catered for by a bifurcation in the direction Ashby has indicated.

Perhaps one should go even further in the interests of applied botany, and after the second post-intermediate year separate those who incline towards mycology and plant pathology from those whose interests are physiology and microbiology. In the third post-intermediate year the physiologists should spend a considerable part of their time in the study of advanced organic chemistry, enzymology, biochemistry and physical chemistry.

It may be necessary eventually to separate off physiology completely as an independent discipline. Such a reform would entail a much closer liaison between the teaching departments in the physical and biological sciences and would necessitate an increase in the staffs of the physics, chemistry and biological departments.

Prof. F. M. Haines, Queen Mary College, London

It is agreed that the curriculum for different types of student should be even markedly different and that the different types of student can be recognized by their preferences and aptitudes at an early stage. At the same time, the first essential is to provide opportunity for studying the subject so far as possible as a coherent whole. In doing so, moreover, some preferences change and further aptitudes develop. The now patent dependence of, for examples, taxonomy on cytogenetics, of cytogenetics on biochemistry, of anatomical structure, life-histories and ecology on physiological principles and so forth, emphasizes the artificiality of segregating different aspects of the subject or divorcing any from the rest.

The principles of the different disciplines should be taught side by side for as long as the corpus of knowledge allows and segregated only to the minimum dictated by teaching convenience. The University of London regulations already allow a choice of ancillary subjects to be followed prior to the attainment of the standard of the General Degree, these being optional and suited to the student's aptitude and outlook ; they also allow a considerable degree of specialization in the final pre-graduate year, in which the born taxonomist need not be tortured by any further physiology, or physiologist by further morphology. Further specialization, or at an earlier stage, is not necessary at all events yet, and though deplorable enough on the grounds indicated above, would be even more so to those who still look to a university course for educational or cultural as well as vocational development.

Prof. T. M. Harris, F.R.S., University of Reading

Dr. Ashby deals mainly with the honours course with supporting subsidiary subjects ; but my direct experience has been with the systems of Cambridge and Reading, where a student reads three equal subjects, takes a degree examination and then possibly a final year on botany alone. However, his remarks apply here also, and I am sure the course is apt to be overloaded.

It is difficult to lighten the B.Sc. General all round without skimping practical work and reading; it seems that some neglect is better. I think this can be left to the student by giving him more choice in examination so that he can safely drop certain fractions of the course. This spares him revision and reading ; but I would make him do nearly all the class work so that he knows what he is doing.

The B.Sc. Special course at Reading is a graduate course for a very few selected students, and as they are allowed to do pretty well what they want, its faults are outside the scope of Dr. Ashby's remarks.

Finally, may I plead for more liberty of choice for the student ? I believe that in the years I have seen, planning has narrowed the field of liberty even in university education, and almost entirely to the detriment of the best students.

Prof. C. T. Ingold, Birkbeck College, University of London

Universities are not concerned with turning out graduates in botany tailor-made for applied research. Those employing botanists should be prepared to select graduates of the right calibre. Their training in the advanced techniques necessary for the particular job should come later.

Some measure of specialization for the student in his final year (not earlier) is desirable and necessary because of the huge body of botanical knowledge. In most universities this is already normal practice. Further, all students should have the intellectual satisfaction of pursuing a small problem in some branch of botany at leisure. This is achieved in many departments by honours students undertaking a 'special study' or 'minor thesis' in the final year or in the preceding vacation.

The division of students into experimentalists and non-experimentalists is highly undesirable. The morphologist, taxonomist, mycologist, geneticist and ecologist, no less than the plant physiologist, must now make the experimental approach to problems. The so-called 'classical problems of morphology'' consisting in the main of theories, which cannot be tested by experiment, concerning the phylogeny of organs and of larger systematic groups, no longer command the attention of many academic botanists.

During their course honours students should have an opportunity of seeing the work of research stations and of the national museums. Students thinking of government employment as botanists should, where possible, undertake vacation work at some research institute or at a national taxonomic centre. This is becoming increasingly common.

DR. W. O. JAMES, F.R.S., UNIVERSITY OF OXFORD

It is difficult to comment constructively on Dr. Ashby's suggestions on account of their point of departure. Honours courses in botany should not be based on his explicit assumptions that the 'bias' of the available staff may be disregarded, and that the courses are a training only for professional botanists. Botany has a much wider value in higher education than self-propagation.

We should not, I think, allow ourselves to be browbeaten by a term, even of so impeccable an appearance as over-specialization. Botany students are of many kinds, not of two only, and a degree of specialization that might poison one may be meat to another. Nothing has impressed me more than the transformation that comes over many students when they pass from the classwork stage to the specialist. The real objection to Dr. Ashby's dichotomy is that it is likely to prove impracticable and seems undesirable. Observation and experiment are still the 'Siamese twins' of botany, and the attempt to dissect them would prove dangerous to the more experimental side and perhaps fatal to the other; much of modern taxonomy and morphology is labelled experimental. Neither does it appear probable that the training proposed for experimentalists would enable more than a few to read many modern papers on photosynthesis. Where two sciences converge, the future lies with those who are willing to co-operate on a basis of knowledge of their own discipline with respect and sympathy for the other. The biologist for the team will be more useful if he is widely trained in biology than if he is given a second-rate knowledge of chemistry and physics.

In a three-year honours course, the first year should be non-specialized in the sense that it ranges over the whole subject. Since students hate the apparent repetitions of a concentric system, it should not be a prospectus to be filled out later, but a definitive treatment of topics chosen for their relative ease of absorption. There should also be courses in methodology with round-the-bench discussion. Collateral reading should be judiciously selected, but could not, I am afraid, lean very heavily on the original publications of the great botanists. Unfortunately, the great botanists have not been great writers, and botany has yet to produce its D'Arcy Thompson.

The two subsequent years should continue with the same collateral plan, the major divisions of botany being built up side-by-side. By the end of the first year most students have discovered their preferences and should be allowed to specialize by a moderate discard of topics. In smaller departments this will inevitably be done for them by the 'bias' of the available staff. On no account should 'dead' lecturing on mugged-up material be tolerated in honours courses. If there is to be a Part I examination, it should come at the end of the second year. This plan I believe to be both more realist and more desirable than a naturalist-from-experimentalist split of the subject.

PROF. F. W. JANE, ROYAL HOLLOWAY COLLEGE, UNIVERSITY OF LONDON

That the honours student is committed to early specialization is incontestable; how early, it is difficult to decide. Modern botany shows a trend toward convergence of its several branches, researches in cytotaxonomy, experimental morphology or biochemical mutants, for example, indicating an increasing synthesis of the various aspects of the subject. Precocious specialization would handicap the student in appreciating this modern approach, and he would be less likely to contribute to its progress later. Moreover, in a science which is becoming increasingly experimental, any attempt to segregate students into experimentalists and non-experimentalists seems neither practicable nor desirable. The best initial equipment for any botanist is surely some understanding of living plants, a recognition that they have form as well as function, an environment as well as a history. Early specialization would not foster this understanding.

If the supply of botanists greatly exceeds the demand, many graduates, despite specialization, are likely to become school teachers, concerned with teaching elementary botany, training in which has now been relegated from the universities to the schools. Here, surely, specialization would even prove a liability.

While the vocational aspect of a university course inevitably bulks large, it should not obscure the need for a purely intellectual training or discipline. I like the individualistic outlook of Mr. J. E. Dale: it implies, and I believe truly, that the worth-while student will follow his own bent and achieve success, in spite of, rather than because of, what his tutors may do to guide him.

PROF. IRENE MANTON, UNIVERSITY OF LEEDS

IN my view the only effective way of increasing the quality of the scientific training of botanists without imposing too early specialization, which would defeat its own ends by unbalancing the teaching in schools, is to make available such resources as are most strongly represented in our best departments to a greater range of students than is now the case. This could, I think, be done most effectively by offering a limited number of post-graduate courses of full-time study of perhaps a year's duration, leading to a special qualification such as the M.Sc. by examination, in certain special fields with exacting technical requirements, for example, advanced plant physiology, cytogenetics or biophysics, taxonomy and/or ecology, to name a few at random, on the lines already initiated by the University of Nottingham in its postgraduate course in mycology, and by the University of Sheffield in its similar treatment of biochemistry. Such courses would precede and be the basis for the narrower and in many ways very different training in research on a specific problem which our present Ph.D. students receive.

Such courses would impose a heavy strain on departments giving them and might perhaps in certain cases be held in alternate years or be shared in some way between several strong departments. Use could also appropriately be made of departments in the Commonwealth since, for example, the University of Malaya might be better placed to offer an intensive postgraduate training in angiosperm taxonomy than a British department. Co-operation and some co-ordination between universities would be essential to prevent overlapping. Some adjustment of postgraduate financing of students would be needed, and in some universities it may be necessary to overcome prejudice against the use of higher degrees for such purposes. If these difficulties could be overcome, the technical qualifications of our best students for careers other than school teaching would be greatly enhanced without disturbance to existing undergraduate curricula.

PROF. J. R. MATTHEWS AND P. J. FAULKS, UNIVERSITY OF ABERDEEN

The steadily increasing content of botanical science suggests the need for a revision of the teaching curriculum, and Dr. Ashby's proposed modifications are a possible solution of a real difficulty. While too early specialization in undergraduate training is to be deprecated, provision should be made in the final year (fourth year in Aberdeen) for a student to receive specific training in a selected branch of the subject. This depends partly upon the student's real interests and aptitudes (which the good student seeking to become a professional botanist will have discovered for himself) and partly upon his proficiency in ancillary subjects.

A fair measure of specialization in the final year will at least enable the student to begin the process of fitting himself for his future career; for no undergraduate course of normal duration can expect to complete the task. Special training, however, is valuable only in so far as it is based upon a sound foundation of botanical knowledge which must be laid in the first three years. All students should receive a *general* training in morphology and physiology, and time can be saved for certain 'modern essentials' if classical theories are not elaborated in the early years. They should also derive from abundant practical illustration, rather than from formal teaching a knowledge of taxonomy, while a 'modern essential' for all students is an introduction to the design and analysis of experiments. The vocational aspect frequently influences the student's final choice of 'specialism', and it should be recognized that not every school of botany can specialize in every branch of the subject.

PROF. R. C. McLEAN, UNIVERSITY COLLEGE, CARDIFF

Dr. Ashby's paper gives expression to a concern that has been steadily growing in the minds of teachers in recent years: how to make terms with the future. The problem can only get worse, and a solution must be found. To continue giving all students a sketch of everything, old and new, is entertaining and may broaden their minds, but it is not the way to train professional botanists. Subsequent speakers did not all appreciate Dr. Ashby's limitation of his argument to that aspect.

There are two ways to meet the situation. One is that of the mathematicians, to confine undergraduate courses to the classical aspects of the subject and leave exploration of the frontiers until the postgraduate period. Unfortunately, our frontiers are too close to us to be ignored, and the alternative obliges us to contemplate some such dichotomies of study as Dr. Ashby suggests. A canalization of interests will be forced upon the botanist as soon as he begins professional life: why not recognize this situation and prepare him for it by better (which means wider) training along the lines of his aptitudes. This is where the bias of staffs comes in—not always illegitimately, I beg to think. I am not impressed by the argument that one cannot distinguish between observational and experimental aptitudes during a student's training. Nearly forty years of university teaching has led me to the contrary opinion.

A broad preliminary course is certainly essential; but those who shake their educational heads over subsequent specialization are ignoring the immense capacity for self-teaching possessed by the good mind. It is quite possible for a physiologist to develop an intimate knowledge of the Bryophyta, for example, on no more than an elementary basis, and we could all multiply instances of men who have successfully combined specialization with broad and varied interests of their own choosing. To broaden his outlook is a man's own task; what he is taught is, happily, not the decisive factor.

PROF. P. W. RICHARDS, UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

I agree with so much of what Dr. Ashby has said that I hesitate to range myself among his critics. The 'dilemma of the curriculum' faces every teacher of a rapidly growing science such as botany; but I think Dr. Ashby's solution is based on a dangerous over-simplification of the real situation. As Mr. Bell said, students do not fall into two classes only—the 'experimentalists' interested in applying physics and chemistry to plants, and the 'naturalists'. Both the needs and the aptitudes of students are more varied than that, and if we forget this and plan the botanical curriculum as Dr. Ashby proposes, we shall provide badly for many who do not belong exclusively to either class, such as geneticists, ecologists and plant pathologists. The ecologist, for example, needs training in plant physiology (except perhaps for its more 'biochemical' aspects) as much as in systematics; but how would he fit into Dr. Ashby's 'dichotomous' curriculum? My own solution would be to divide the subject not into two, but into seven or eight, branches and allow the student to specialize in a reasonable number of these.

Apart from objections in principle, I foresee great difficulties in applying Dr. Ashby's suggestion, except in a very large and well-staffed department. In one such as my own without a large staff, and in which future professional botanists form only a small minority of the students, these difficulties would probably be insuperable.

Prof. M. Skene, University of Bristol

Dr. Ashby's acute analysis is very welcome. The problems arising from the increasing amount and range of knowledge are felt by all botanists. There may be less agreement on the solution suggested; indeed, it may be that no uniform plan is desirable.

In undergraduate work we should educate botanists and not train them for particular botanical jobs. All undergraduates should have the same general education. The morphologically minded should gain good experience in experimental work; the physiologist should know how to handle a variety of plants. Natural bias in ability and interest can be allowed for in the setting of the examination papers.

Botany is the meeting-ground of many sciences, and the advantage of this in a liberal education should not be lost: nor is the dichotomy so sharp as Dr. Ashby suggests. The plant pathologist is a good example of a specialist who must be competent in both fields.

The exhaustive study of a few types is valuable in giving depth; but the method should be judiciously tempered by opportunities for getting to know a large variety of material. Diversity of creatures is the essence of living Nature, and, to many, the spice of biological study.

The employers of botanists should not expect the new graduate to be ready trained for a special job. The necessity for this training remains. It would best be met by postgraduate diploma courses of about one year's duration. Such courses might well be shared out between the universities. For very many graduates they would be more useful than the years spent in research leading to a higher degree.

Prof. M. Thomas, F.R.S., King's College, Newcastle upon Tyne

The few words available may be used most economically to state present practice at King's College, Newcastle upon Tyne, in framing "honours courses in botany considered solely as a training for professional botanists (not including school teachers)", to which Dr. E. Ashby limited the scope of his address. We have been experimenting for a number of years, and realize that there is much scope for further experiment.

At present we require all honours students to study all post-intermediate courses given over two complete sessions in the Department of Botany. They all thus cover the ground for the final pass (general) examination. In their third and final year each honours student is informed that about two-thirds of the course is the maximum he can be expected to cover. Experience has shown that the combination of interests varies with the student. The special study of taxonomy has been combined with that of molecular events.

Our view is that the problem of each honours student requires individual consideration, which is extended to the selection of auxiliary subjects. We consider that some knowledge of chemistry is desirable for all; but chemistry is not a compulsory subject. Intending physiologists often extend their chemical studies over two years. As regards our other specializations, zoology has been the most favoured subject for two years of study by intending cytogeneticists and field ecologists. Bacteriology has been studied with much profit by students now carrying out graduate research in mycology. Students having the necessary mathematical ability have been encouraged to study physics above an elementary level.

More than ten years ago two students of special honours quality graduated in what might be regarded as a joint honours school in physics and botany, and another student in chemistry and botany. Unfortunately these combinations of subjects have not been taken in recent years. A case could be made for such schools rather than special honours in botany for certain picked students competent to study physical as well as biological science to a high level.

Prof. T. G. Tutin, University College, Leicester

I cannot altogether agree with Dr. Ashby that the solution of our difficulties lies in earlier specialization. Taxonomists and morphologists are at last applying experimental methods to their studies, and some knowledge of mathematics, physics, chemistry and plant physiology is essential if they are to make real progress.

It is of particular importance in this connexion that the chemistry which botanists learn should include more physical and organic chemistry and less about the lead-chamber process.

For a sound training in botany a four-year course seems desirable to-day, if financial considerations will permit it; the first two years can then be spent on a general course in three subjects, chosen in accordance with the special interests of the student, the next year on a wide botanical course and the final year in specializing in a particular part of the subject. Recent experience here has clearly demonstrated the great value to the student of being able to spend four years over the degree course. The acceptance by many universities of the General Certificate of Education at Advanced Level as a substitute for Intermediate greatly increases the desirability of a four-year degree course, since students often arrive at the university with little real foundation for their subsequent studies.

A less satisfactory, though perhaps more practicable, alternative might be to retain the three-year course with a less detailed treatment of the groups of cryptogams in the first two years and then to allow considerable specialization in the final year.

Finally, would it be unkind to suggest that the pure "naturalists" with no aptitude for experiment or interest in physical sciences should be encouraged to take an arts degree and pursue botany as a hobby?

Prof. D. H. Valentine, Durham Colleges in the University of Durham

I am in general agreement with Dr. Ashby's proposals; but I would suggest some modifications. First, I do not think an honours student should choose his subject until, at earliest, the end of his first year at the university; it is not uncommon for a student to change his mind about his subject, and I think it is well that he should be able to do so. Secondly, I think that it is most undesirable to widen the division between botany and zoology, as Dr. Ashby seems to suggest. On the contrary, I think the subjects should, so far as possible, be brought closer together. Thus, I should like to make it possible for students who have had a good introductory training in both disciplines to specialize in their final year in, say, evolutionary studies, or animal and plant ecology, or cell physiology; the courses would be provided jointly by both botany and zoology departments, with assistance from other departments where it was required.

PROF. W. T. WILLIAMS, UNIVERSITY OF SOUTHAMPTON

I strongly support Dr. Heslop Harrison. There is room for a continuous spectrum of botanists, ranging from the pure morphologist to the biochemist, and it is the traditional task of any one of these to bring his chosen problem one stage nearer to the realm of the chemist. The rigid segregation of students into two groups, whatever its organizational advantages, might easily result in morphologists who are not interested in the physiological problems underlying their study, and in physiologists who are largely unaware of the vast fields of experimental morphology awaiting investigation. If a student genuinely wishes to specialize early, encourage him; but let us at all costs attempt to retain the possibility of training good general botanists, however difficult this may be.

OBJECTIVITY OF COLOUR PREFERENCES*

By DR. G. W. GRANGER
Psychology Dept., Institute of Psychiatry, Maudsley Hospital, London, S.E.5

It has long been supposed that colour preferences are entirely a matter of personal taste, depending on individual associations and other subjective factors, and the results of numerous experimental studies have seemed to support this view. Thus, Chandler[1] in his survey of research on colour preferences remarks that the results of these experiments are "chaotic"; the most careful and thorough work of such acknowledged authorities as von Allesch[2] serves only to emphasize the fact that observers disagree sharply as to the relative preferential value of single colours and colour combinations.

This apparent lack of agreement has led those psychophysicists and sensory psychologists who have explored in great detail the 'objective' stimulus dimensions of colour to dismiss the æsthetic, affective or preferential values of colours as purely subjective and outside the scope of present-day scientific analysis. For quite different reasons, æstheticians and psychologists of *Gestalt* persuasion have declared the whole realm of colour æsthetics to be beyond analysis by the ordinary atomistic and dimensional methods of science. Such writers argue that this field is characterized by "emergent properties" which cannot be accounted for in terms of parts and relations between parts as Spearman[3] and other elementalists have claimed; at every turn the investigator is confronted by *Gestalt* or whole qualities that defy analysis.

Recent experiments by the author suggest that neither of these two extreme views, the subjective nor the *Gestalt*, is justified; indeed, the evidence seems overwhelmingly in favour of objective and fairly atomistic hypotheses. As detailed accounts of the individual experiments on which this evidence is based will be published elsewhere, only a general summary will be presented in this paper.

In the first experiment, sixty sets of standard Munsell colours were selected to represent the entire colour solid along its three principal dimensions: hue, lightness and saturation. Within each set the colours were ranged in order of preference by fifty subjects (twenty-five men and twenty-five women) of normal colour vision, as tested by the Ishihara[4], Rabkin[5], and Farnsworth–Munsell[6] tests. Illumination at 6,500° K. was provided by a specially calibrated tungsten lamp in conjunction with a Macbeth daylight filter, and the colours were viewed against a neutral grey background of Munsell value 5. When subjects' rankings were summed for each set and the amount of agreement calculated in terms of Kendall's[7] coefficient of concordance (W), it was found that the resulting coefficients reached significance at the $P < 0{\cdot}01$ level, indicating quite clearly that the subjects were not independent in their preferences; on the contrary, they showed a remarkable degree of concordance, the average value of W being about 0·3. Further, it appeared that the general order of preference for any one attribute of colour (which remained invariant at different levels of the colour solid) was dependent on stimulus properties in the following way: hues of shorter wave-length tended to be preferred to those of longer wave-length, the more saturated colours were preferred to the less saturated, and colours which contrasted least in lightness with the background were ranked higher than colours showing maximum contrast. Conclusions were necessarily tentative, owing to the small number of items involved in the general order of preference. Contrary to some earlier claims, no marked differences were found between the preferences of men and women.

A second experiment was undertaken in which preference judgments were obtained from twenty subjects for four sets of colour combinations. Three of the sets represented variation along each of the principal dimensions of colour, while the fourth contained fully saturated hues which had been used in a previous experiment by Clarkson, Davies and Vickerstaff[8]. Preference judgments for the hue, lightness and saturation tests were obtained against a background of neutral grey, while preferences for the combinations of fully saturated hues were obtained against a black background to facilitate comparison with the previous research in which this type of ground had been used. Data for all four tests were collected, as in the first experiment on single colours, under an approximation to C.I.E.[9] illuminant *C*. When subjects' preferences were analysed, it was found once again that a large measure of general agreement existed for all four types of colour combination used in the experiment, and, as before, the general order of preference seemed to be dependent on objective stimulus properties: thus, preference tended to increase with increasing hue distance between the component colours making up the combinations, to decrease with increasing lightness, and to decrease with increasing saturation. This dependence was most striking in the case of hue combinations, where there was an almost perfect positive correlation between preference judgments and the size of hue interval between the components. Particularly encouraging was the independent confirmation of results obtained earlier by Clarkson, Davies and Vickerstaff. From data kindly supplie by Dr. T. Vickerstaff, it was possible to calculat correlations between preference judgments and hu interval, and when this was done, the resultin coefficients exceeded 0·95—somewhat larger tha those I have obtained for combinations of full saturated hues.

Finding that preferences for combinations of hue could be accounted for almost entirely in terms the interval between the component colours in the case where one component remained constant for a given series, it was decided to consider the more general case in which not only the interval or relation between the components varied from one combination to another, as in the second experiment, but also in which the component colours were both allowed to vary throughout a given series. Could preference be accounted for at this more complex level ? Moon and Spencer[10], two recent theoretical writers on colour harmony, have claimed that such prediction is possible and, on the basis of certain assumptions concerning the various classes into which harmonies can be divided and Birkhoff's[11] work on 'æsthetic measure', they have developed an 'æsthetic formula' for colour combinations. Unfortunately, this formula, like its earlier counterpart for polygonal figures, leans too heavily on deductive procedures which fail to take into account results of empirical research in æsthetics : in consequence, when submitted to experimental test, its predictive value proved to be negligible. However, a simpler formula, derived not from assumed higher principles but from the results of previous experimental work on 'hedonic summation' and colour harmony, was found to account for the major part of the variance (70 per cent) without taking into account the lack of perfect reliability in the subjects' preference judgments. This formula, conceived along frankly atomistic lines, depended upon two sets of factors : (1) preference for the component colours, plus (2) a relational term concerning the combination as such ; in Spearman's words, upon 'fundaments' and the 'relation' between them.

---

* Substance of a lecture to the Colour Group of the Physical Society delivered on February 13.

Further evidence of the objectivity of colour preferences was found in experiments on the influence of background and area. It will be remembered that the experiment on the general order of preference for single colours was carried out under one background condition, namely, a neutral grey of Munsell value 5. But it cannot be assumed without proof that a general order of preference occurring under one condition of background will remain invariant under other conditions. Observation suggested that the order would remain relatively constant only when the general colour–ground relationship was unchanged. Experimental tests of this hypothesis were made using several different achromatic and chromatic backgrounds and, in general, the evidence tended to support it. Further, it was possible not only to predict *when* a significant change in preference would occur, but also, to some extent, the direction it would take, on the basis of results obtained earlier in the experiments on preferences for single colours and colour harmony. As before, there was a substantial measure of agreement between subjects' preferences.

The influence of area was studied in relation to colour harmony. The importance of this factor is generally recognized both by æstheticians and practising artists, who often claim that ". . . the choice of quantity is more important than the choice of colour"[12]. From the practice of artists, an empirical 'rule' has developed concerning the proper balance of areas in a colour design : the accepted principle is that a large area of colour at a low degree of saturation will balance a small area of highly saturated colour ; the principle is sometimes extended to lightness—balancing of the darks against the lights. When stated in quantitative terms, this principle is of particular interest to experimental æsthetics, and my experiments were designed to test the predictive value of two 'formulæ' that have been proposed. The first formula was developed by A. H. Munsell[13], founder of the Munsell colour system, who stated his 'rule' for area balance in the following way : ". . . the stronger the color . . . the smaller must be its area ; while the larger the area, the grayer the Chroma. Thus R 7/6 balances R 3/3 in the proportion of nine parts of the lighter red to forty-two parts of the darker red. In other words, these symbols will balance colors inversely as the product of their factors". The second formula, proposed by Moon and Spencer[14], is rather more elaborate ; these authors claim that a pleasing balance is obtained when the product of each area and its distance from the 'adaptation point' in colour-space is the same. The colour-space to which they refer is a metric-space, developed by making a mathematical transformation of the C.I.E. colour-space.

In order to test these two hypotheses, pairs of Munsell colours were presented to a group of subjects, who were asked to adjust the areas of the two colours in each pair to give the most pleasing balance. Results showed, first, a large amount of concordance between subjects' preferences and, secondly, the superiority of Munsell's empirical 'rule' over Moon and Spencer's formula : whereas Munsell's formula accounted for about 40 per cent of the total variance, Moon and Spencer's gave very small and insignificant correlations between observed and predicted preferences.

Finally, an attempt was made to link results of some of the experiments on colour appreciation with preferences for more complex visual material. The method adopted was first to derive 'scores' for subjects who had taken part in the experiments on preferences for single colours and colour harmony by correlating individual preferences with the general order of preference (a procedure for which justification has previously been given by Eysenck[15] and other investigators of general æsthetic appreciation), and then correlating these scores with scores on the Maitland Graves test of design judgment[16], which involves the ranking of black-and-white designs. Both correlations, between preferences for single colours and design judgment, and between preferences for colour combinations and design judgment, were significant and fairly high, being 0·60 and 0·73, respectively. Although based on a small number of cases, these positive correlations suggest that preferences for elementary colour stimuli may be dependent on an æsthetic factor of a fairly comprehensive kind ; they also do something to counter the assertion, often made by theoretical æstheticians, that the experimental æsthetics of simple sensory stimuli has no bearing on the problem of æsthetic appreciation, especially as the design judgment test used in this experiment has been shown to have a considerable degree of validity when measured against acceptable external criteria.

The main conclusion which seems to follow from the results of these experiments is that colour preferences are objective in the sense that (*a*) they are to a considerable extent independent of personal taste, and (*b*) are dependent to some degree on inherent stimulus properties ; there is no experimental justification for an extreme subjectivist point of view in this field. This suggests that preferences rest on a firm biological foundation in the perceptual equipment of the individual, and such an interpretation gains support from the re-analyses made first by Eysenck[17] and later by me (using different statistical techniques) of data on the colour preferences of subjects from widely different backgrounds and even from different culture patterns: the evidence everywhere indicates a substantial measure of agreement. Results show quite convincingly that the conclusions reached by von Allesch, Chandler and others, and referred to earlier in this paper, were not warranted by their own data; they were arrived at on the basis of inadequate statistical procedures. Finally, there seems to be no justification for an extreme *Gestalt* point of view in this field, for preferences can be accounted for in terms of quite atomistic concepts of relations and fundaments, and knowledge derived from elementary colour stimuli can be applied to preferences for material of a more complex nature. The value of this demonstration may extend beyond the realm of experimental æsthetics to other parts of the psychological field in which problems of organization are encountered; thus, the relevance of these studies to the problem of personality organization has already been considered by Eysenck in a recent publication dealing with "The Scientific Study of Personality"[18].

OBITUARIES

Dr. W. T. Calman, C.B., F.R.S.

WILLIAM THOMAS CALMAN, who died suddenly on September 29 in his eighty-first year, was a great zoologist. A distinguished pupil of the late Sir D'Arcy Thompson, he was well known as the leading British carcinologist of our time, author of the volume on "Crustacea" in Lankester's "A Treatise on Zoology" (1909) and of "The Life of Crustacea" (1911).

Born at Dundee in 1871, Calman was educated at the High School and, after a spell as clerk in an insurance office, at University College, Dundee (later to become one of the constituent colleges of the University of St. Andrews). On obtaining his B.Sc. in 1895 he was appointed assistant lecturer and demonstrator in zoology, a post which he held until 1903, taking his doctorate in 1900. There he acquired valuable teaching experience and a sound knowledge of zoology which many learned to appreciate in later years.

When he joined the staff of the British Museum (Natural History) in 1904, he was placed in charge of the Crustacea—a group which he had already made his own—and the Pycnogonida, and for a short time he was responsible for the Arachnida as well. In addition to his official duties, he for many years compiled the Arachnida and Crustacea sections of the *Zoological Record*, and it was astonishing how well he remembered references twenty or thirty years later. In 1921, the year in which he was elected to the Royal Society, he became deputy keeper of the Department of Zoology, and in 1927 he succeeded Regan as keeper, a post which he held until his retirement in 1936. In the previous year he had been created a C.B., and in 1937 was elected an honorary Fellow of the Royal Society of Edinburgh.

Calman also took a prominent part in scientific activities outside the Museum. He served on the Council of the Royal Society and as external examiner to several universities. For twenty-seven years he was secretary to the Ray Society, and at the time of his death was an editor of the *Annals and Magazine of Natural History* and a member of the International Committee on Zoological Nomenclature. His longest association was with the Linnean Society of London, of which he was zoological secretary (1923–28), president (1934–37) and Linnean Gold Medallist. At the 1930 Bristol meeting of the British Association he presided over Section D (Zoology).

In a presidential address to the Quekett Microscopical Club, Calman tells us that he was an amateur microscopist before he began the serious study of zoology. D'Arcy Thompson chanced to hear him speak on rotifers and, recognizing his aptitude, made it possible for him to enter the University. After graduation he turned his attention chiefly, though by no means exclusively, to the Crustacea. From 1896 onwards he contributed a steady stream of papers of the highest order. His work impresses not so much by its quantity—several of his contemporaries were more prolific writers—as by its intrinsic qualities. These are already apparent in his earliest papers, notably that in which he demonstrated with remarkable insight the affinities of the recently discovered *Anaspides* with the fossil Syncarida. They appear at their best in the "Treatise" volume which all specialists regard as his masterpiece. The book is much more than a lucid, concise, masterly synthesis of what was known at the turn of the century. Calman possessed, to a degree that has rarely been equalled, a gift for winnowing the significant from masses of detail. He revealed much of the order beneath the diversity of the subclass Malacostraca; the new classification which he introduced in a small paper published in 1904 was accepted, and, with the addition of the small order Thermosbaenacea to the division Peracarida, still stands. Much of his later work was concerned with the elucidation of the more obscure orders of the Malacostraca and with the phylogeny of the Arthropoda. He also wrote on marine boring organisms injurious to submerged structures, and on the Pycnogonida.

Calman had hoped to continue his research work after his retirement, and did, in fact, report on the Pycnogonida and Caridea of the *John Murray* Expedition. Later, however, he moved to Tayport, Fife, and soon we find him acting as temporary war time lecturer in zoology in his own Alma Mater, of which he was an LL.D. A series of lectures delivered to his students on "The Classification of Animals" appeared in book form in 1949.

As administrator of a large museum department, subordinates of all grades found him most approachable. To the younger zoologists of his staff he gave freely of his time, knowledge and experience, and as an editor he excelled. Sociable by nature, he liked to meet all visitors to his Department, whether student or foreign specialist (with whom on occasion he had to converse in Latin). All who knew him appreciated his profound erudition, his great personal charm and his sense of humour. His memory is held in affectionate esteem by all who came under his influence.

In 1906 he married Miss Alice Donaldson, of Tayport, who, with a son and a daughter, survives him.

I. GORDON

Prof. F. C. Lea, O.B.E.

PROF. F. C. LEA, emeritus professor of engineering in the University of Sheffield, died on September 30 at the age of eighty-one.

Frederick Charles Lea was born near Crewe and was apprenticed in the Mechanical and Electrical Departments of the London and North Western Railway. He received his scientific education at Owens College, Manchester, and the Royal College of Science, London. He was Senior Whitworth Scholar in 1896. After a further period with the London and North Western Railway, he became in 1900 senior assistant to Prof. W. C. Unwin at the City and Guilds of London Central Technical College. In 1908 he published the text-book on "Hydraulics" by which his name became known to engineering students all over the world. During 1911–13 he served as one of H.M. inspectors of technical education and in 1913 was appointed professor of civil engineering in the University of Birmingham.

During the First World War he held commissions, first in the Territorial Force and afterwards in the R.N.V.R. and in the R.A.F. He made a special study of materials for aircraft and was concerned in the development of all-metal aeroplanes.

In 1923 Prof. Lea was appointed professor of mechanical engineering in the University of Sheffield, and was dean of the Faculty of Engineering until his retirement in 1936. During this period he carried on experimental research, in association with a succession of students, in several fields related to the mechanical properties of metals, and he published numerous papers on such subjects as fatigue, embrittlement, welded joints, springs, and notably creep at high temperatures.

During his career, Lea took a lively interest in scientific and technical societies, and was perhaps specially attached to the British Association and to the Institution of Mechanical Engineers. He was president of Section G (Engineering) of the former in 1929 and of the Institution in 1944. He served on many committees and consultative bodies concerned with technical and educational matters, and had a considerable part in the development of the National Certificate schemes. During 1936–50 he was a director of Edgar Allen and Co., Sheffield.

Lea's contribution in the field of engineering science was a dual one: on one hand, he was a skilful and energetic experimental investigator with a wide range of interests; on the other, he was a progressive technical educationist and a particularly able teacher. His influence to-day is probably mainly felt through the hundreds of engineering graduates to whom he communicated enthusiasm and the spirit of inquiry.

In his personal life, Lea was a deeply religious man and had a high sense of social duty. Throughout his life he was an active member of the Methodist Church, and he served it in many capacities both in administration and as teacher and speaker. For several years he presided over the Sheffield Council for Social Service.

Mr. Peter Doig

WE regret to announce the death on October 13, after a long illness, of Mr. Peter Doig. He was born in 1882 in Glasgow, where he received his primary education and later he was trained as a draughtsman at the shipyard of John Brown and Co., Ltd., at Clydebank. He then worked at Harland and Wolff's, Belfast, and afterwards at shipyards in Shanghai, where a serious breakdown in health in 1916 necessitated a temporary rest, and he returned to Clydebank, travelling by the Trans-Siberian Railway to Europe. After working for a time at Beardmore's, he went to the United States, and on his return was appointed in 1918 general secretary of the Association of Engineering and Shipbuilding Draughtsmen. He did very good work on screw propeller design, on which he had specialized; but unfortunately ill-health compelled him to retire from the secretaryship of his Association in 1945.

Doig was a keen astronomer, and was elected a member of the British Astronomical Association in 1921 and a Fellow of the Royal Astronomical Society the following year. In 1930 he was appointed editor of the *Journal of the British Astronomical Association*, a position which he held until 1937, when the pressure of work with his professional Association compelled him to resign; but in 1948, after his retirement as secretary of his Association, he was re-appointed editor of the *Journal* and continued with this work until his death. He was an excellent editor, and made considerable contributions himself to the *Journal* in the form of reviews and notes from numerous astronomical publications in various parts of the world. During 1928–41 he was also honorary curator for the British Astronomical Association. In 1927 his book, "An Outline of Stellar Astronomy", was published, and an enlarged and revised edition appeared in 1947; in 1950 "A Concise History of Astronomy" was published, a book which deals with the history of astronomy from the earliest times up to recent years. During 1951–52 he collaborated with eleven other astronomers—each an authority in his own particular subject—in the production of a work on astronomy in which he was responsible for the larger portion of the chapter on the historical side and sole author of the chapter on the stars; he had corrected the paged proofs shortly before he died.

In 1909 Mr. Doig married Mary Scott, who, with a married daughter, survives him.

WE regret to announce the following deaths:

Prof. J. G. Lawn, C.B.E., president in 1930 of the Institution of Mining and Metallurgy, on October 21, aged eighty-four.

Prof. Ernest Vessiot, member of the Mechanics Section of the Paris Academy of Sciences and formerly director of the École Normale Supérieure, Paris, on October 17, aged eighty-seven.

NEWS and VIEWS

Nobel Prize for Physiology and Medicine for 1952 : Prof. S. A. Waksman

THE Nobel Prize for Physiology and Medicine for 1952 has been awarded to Prof. Selman Abraham Waksman, professor of microbiology and head of the Microbiology Department of the College of Agriculture and Experiment Station at Rutgers University, New Brunswick, N.J., for his discovery of streptomycin, the first effective antibiotic against tuberculosis. Prof. Waksman was born in 1888 in Priluka, a small town in the Ukraine, emigrated to the United States in 1910 and became a naturalized citizen there in 1915. The whole of his scientific life since 1911 has been spent at Rutgers University and has been devoted to the study of microbiology, and particularly to that group of soil micro-organisms which are frequently spoken of as ray fungi and belong to the genus *Actinomyces* or *Streptothrix*. Following the discovery of penicillin, which is fully effective only against Gram-positive bacteria, Waksman and his collaborators began, in 1939, a systematic search for an antibiotic active against Gram-negative bacteria and found it, in 1944, in streptomycin, a metabolic product of *Streptomyces griseus* (formerly known as *Actinomyces griseus*). They also showed that streptomycin is highly active *in vitro* against *Mycobacterium tuberculosis*. This observation was quickly followed by the proof by Feldman and Hinshaw that streptomycin exerts a powerful suppressive action in experimental tuberculosis in guinea pigs, and finally by the demonstration by many investigators of its effectiveness in the treatment of different types of tubercular infections in man. Thus, in spite of some imperfections, streptomycin offered the first real hope of chemotherapeutic treatment of a disease which was formerly almost universally fatal.

G. A. Mantell, F.R.S. (1790–1852)

GIDEON ALGERNON MANTELL, who died a century ago, on November 10, 1852, belongs to that interesting band of medical men who have won both fame and popular applause in extra-professional pursuits. Son of a Lewes shoemaker, he was born on February 3, 1790. After serving as apprentice to a local surgeon and studying at St. Bartholomew's Hospital, London, he qualified M.R.C.S. in 1811 and thirty-two years later was elected one of the original three hundred Fellows of the Royal College of Surgeons. A busy medical practitioner in Lewes and the surrounding countryside, Mantell made many valuable contributions to geology, collecting specimens from the chalk around Lewes and from the Sussex Weald, sending reports to the Linnean Society, and building up a private geological museum, which he later sold to the British Museum for £5,000. A pioneer in the study of fossils at a time when this was regarded as impious, he is known for his discovery in the sandstone of Tilgate Forest of the iguanodon, which he reported to the Royal Society in 1825. A popular lecturer and a facile writer, his works, some of which went through several editions and were illustrated by plates engraved by his wife, include "The Fossils of the South Downs" (1822), "Thoughts on a Pebble" (1837) and "The Wonders of Geology" (1838). Mantell played a leading part in securing a free pardon for Hannah Russell in the Burwash case, and published his "Observations on the Medical Evidence Necessary to Prove the Presence of Arsenic in the Human Body" (1827). He was elected to the Royal Society in 1825 and was awarded a Royal Medal in 1849; he received the honorary LL.D. of Yale University in 1834. A victim of extreme lateral curvature of the spine, which made him hypochondriacal and acrimonious, Mantell died of an overdose of opium.

British Museum (Natural History) : Appointments

THE Trustees of the British Museum have promoted Mr. Wilfred Norman Edwards, keeper of the Department of Geology at the British Museum (Natural History) to the rank of deputy chief scientific officer, with effect from December 1; Mr. Edwards will continue to hold the keepership of geology. The Principal Trustees have also appointed Dr. Frederick Allan Bannister to be keeper of the Department of Mineralogy; and Mr. Alexander Cockburn Townsend to be deputy keeper in charge of the Library of the British Museum (Natural History) both with effect from December 1. Mr. Edwards was a scholar of Christ's College, Cambridge, where he took first-class honours in the Natural Sciences Tripos in 1911. He entered the Museum in 1913 and has been keeper of the Department of Geology since 1938. He has specialized in fossil plants. Dr. Bannister was educated at Clare College, Cambridge, and took a first class in both parts of the Natural Sciences Tripos in 1922 and 1923. He entered the Museum in 1927 as an assistant keeper and has specialized in the analysis of mineral structure by means of X-rays, in the development of which method he has taken a leading part. Mr. Townsend was educated at Shaftesbury Grammar School, St. Paul's School and Magdalene College, Cambridge. He obtained second-class honours in the Classical Tripos in 1926 and in the Modern Languages Tripos in 1928. He entered the service of the Trustees in 1930. During 1931–39 he was honorary secretary of the University and Research Section of the Library Association, and since 1948 has been honorary secretary and editor of the Society for the Bibliography of Natural History.

Groundnuts Scheme in East Africa

IN the House of Commons on October 29, a written reply was given to a question by Mr. A. R. Hurd asking the Secretary of State for the Colonies if he was satisfied, after another season's operations at the Kongwa, Urambo and Nachingwea centres of the East African groundnut scheme, that the large-scale experimental development proposed in Command Paper No. 8125, January 1951, was practicable; and if the policy and financial provisions then decided for the scheme had been adopted by the Government. Mr. J. G. Foster, Under-Secretary for Commonwealth Relations, stated that neither the board and chairman of the Corporation nor the Secretary of State is satisfied with the scheme as laid down. The experimental data which it was the object of that scheme to provide can certainly be obtained; but the board considers that there are fundamental agricultural problems in Urambo and Nachingwea which should be worked out on a lesser scale. The board is considering revised plans for this purpose which will keep the cost within the balance remaining of the £6 million. These should be available by December and the Secretary of State will then make a further statement.

Cartographical Needs of the Airman

The activities of the Institute of Navigation include the investigation of various problems by working-parties under the general guidance of the technical committee, and several of these were referred to by Rear-Admiral A. Day, Hydrographer of the Navy, in his presidential address to the Institute. One working-party has undertaken to inquire into the precise requirements the airman needs of his maps and charts. The nautical chart has been built up to its present shape by many centuries of knowledge and experience of what the seaman wants. The air chart, like aviation itself, has grown up quickly, so that just what it should be like and exactly what is wanted of it has not been so easy to establish without question. The basis from which the Institute's working-party proposes to begin its investigations is one that accepts air navigation as it is to-day, but does not necessarily relate it to a system which uses charts in their present form. This means that their examinations will go much deeper than merely questioning whether, say, a map used for aircraft operating at a height of some 40,000 ft. should give the characteristics of lighthouses, or should show the 100-fathom line. Another problem is how to determine the quickest flight-path from one place to another, a problem which bears directly on the economy and efficiency of navigation in long-distance flights. A workable method of being able to determine, for any given set of meteorological conditions, the route of least time would be of considerable assistance to air operators. For some time now the Institute has had a working-party investigating the whole problem of determining the optimum flight-path; the task is a long one, partly because the aim is to produce a practical method which will offer clear advantages over those used in flight-planning to-day.

Oil in Pakistan

A speech on the development of the oil industry in Pakistan was recently given in Karachi by M. J. Condon, chairman of the board of directors of Pakistan Petroleum, Ltd. The sole producing region is the Potwar Basin, south-west of Rawalpindi, where four fields are established—Khaur, Dhulian, Balkassar and Joya Mair—but production is relatively small. Exploration is, however, active, six major tests being in operation at Bains and Chak Naraung in Punjab, at Sui in Baluchistan, at Patharia and Sylhet in East Bengal, and at Patiya near Chittagong. Mr. Condon's forecast on these prospects does not, however, appear particularly optimistic. As he rightly points out, prospecting costs in Pakistan are fifteen times what they are in the United States, primarily because all plant and equipment has to be shipped to the former country from overseas whereas "in America these things are available to the end of a telephone line", a pertinent comment on petroleum economics in other countries besides Pakistan. There is the prospect of a refinery being erected in Karachi, and a technical commission is being set up to review the whole situation. It is clear that the Pakistan Government and the industrial enterprises concerned are doing everything possible to develop petroleum resources in this geologically difficult territory.

An Atlas of the Asclepiadaceæ

Under this title, and with the help of some seventeen maps, Prof. R. Good (*New Phytologist*, 51, 198; 1952) has illustrated the distribution of the family, sub-families, tribes and selected genera of this highly distinctive group of tropical plants. The Asclepiadaceæ, by some taxonomists included in the order Apocynales, include perennial herbs, undershrubs, shrubs and climbers, all having a specialized pollen-transfer mechanism. Because of their particular and highly unusual features, the two constituent sub-families thus afford very useful materials for geographical study. The maps represent a summation of all available information regarding the distribution of the family. The family has a general distribution both in the Old and New World tropics, and of its two sub-families the smaller is confined to the Old World, while the larger is present in both hemispheres. The family, however, is poorly represented in isolated islands. The proportion of narrowly distributed or endemic genera is very high, some being very local; that of endemic species is even higher, no such species being common to both worlds.

A New Circumpolar Plant Species in Scotland

With the discovery in 1951 of *Diapensia lapponica* L. (Ericales) at 2,500 ft. in the Arisaig district of Inverness-shire, Scotland, a new species, genus and family have been added to the British flora. Several hundred specimens have now been observed in this locality, the habitat being completely exposed, on stony and gravelly schists, and with a rainfall of 120 inches. *D. lapponica* is one of the small group of circumpolar, arctic-montane species—a group not represented in the mountains of Central Europe—with a wide distribution in the several continental and insular areas in the Arctic region (see J. Grant Roger, "*Diapensa lapponica* in Scotland", *Trans. Bot. Soc., Edin.*, 36, Pt. 1, 34; 1952).

N.P.L. Colour Temperature Scale

In July of this year the Director of the National Physical Laboratory announced that in future the 1948 International Temperature Scale would be used in assigning colour temperatures to light sources calibrated at the Laboratory. Previously, the 1927 International Temperature Scale had been used. The Laboratory has now issued the following comparisons and conversion factors. Corresponding values of temperatures on the two scales, in the range of importance in the calibration of tungsten filament lamps, are as follows:

1927 Scale	1948 Scale
1500·6° K.	1500° K.
2003·8	2000
2508·6	2500
3015·1	3000
3523·7	3500

If a lamp has been found by calibration to give a particular value of colour temperature on the 1927 Scale when it is run at a certain voltage V, the voltage to give the same numerical value of colour temperature on the 1948 Scale is obtained by multiplying V by the factor shown in the following table:

Colour temperature (° K.)	Multiplication factor for voltage
1500	1·001
2000	1·005
2500	1·009
3000	1·014
3500	1·019

These factors may be taken as correct to about one-tenth of one per cent.

Illuminant A. The factor by which the voltage of a lamp calibrated at 2848° K. on the 1927 Scale must be multiplied to give 2854° K. on the 1948 Scale (the current definition of colorimetric illuminant *A*) is equal to 1·018.

Scottish Postgraduate Scholarship Awards in Agriculture

THE Department of Agriculture for Scotland has awarded the following postgraduate scholarships in agricultural subjects, tenable for periods up to three years, commencing October 1 at the university or institute shown: ***Agricultural Economics***, A. V. Vickery (Agricultural Economics Research Institute, Oxford); ***Husbandry***, J. Eadie and A. O. Ballantyne (continuation of current award) (University of Edinburgh), D. S. Hay and R. R. Shepherd (University of Cambridge), R. Laird and T. D. MacLean (University of Reading), and A. F. Gristwood (continuation of current award) (Ohio State University); ***Statistics***, St. C. S. Taylor (continuation of current award) (University of Edinburgh).

University of London

THE following announcements have recently been made from the University of London: the title of reader in mechanical engineering has been conferred on H. Hampson in respect of the post held by him at Queen Mary College; the degree of D.Sc. has been conferred on Miss Olive N. Purvis (Imperial College of Science and Technology) and C. A. Rogers (University College).

University of Leeds

THE University of Leeds has conferred the title of emeritus professor upon Prof. J. W. McLeod on the occasion of his retirement from the Brotherton chair of bacteriology. The following have been appointed lecturers in the University: Dr. R. W. Owen (zoology), F. R. Mobbs (mechanical engineering), and G. Hay, G. W. Reed and Miss Margaret T. Morrison (medical physics).

Fourteenth International Congress of Zoology, Copenhagen

THE Fourteenth International Congress of Zoology will be held in Copenhagen during August 5–12, 1953, under the presidency of Prof. R. Spärck, with Dr. Anton Fr. Bruun as secretary-general. It is proposed to hold three general meetings for all members of the Congress; but otherwise the proceedings will be divided into various sections, each dealing with specialized topics. Two excursions to West and East Jutland have been planned after the Congress, and possibly a third one to study marine fauna of the deeper part of the Skagerrak; no excursions will take place before August 5. Membership fee for the Congress is 100 Danish kroner (approximately £5 5*s*. or 15 dollars).

Conference on Race Problems

THE British Social Biology Council is holding a one-day conference on Saturday, December 6, on race problems. The subject will be approached from three angles: the biological, the psychological and the anthropological. The main speakers will be Dr. A. F. Mourant, Dr. Kenneth L. Little, W. R. Bion and M. Freedman. Chairmen will include Dr. Julian Huxley and Dr. B. W. Gussman. The conference will be held in the Chemistry Lecture Theatre at University College, London, and tickets can be obtained from the Secretary, British Social Biology Council, Tavistock House South, Tavistock Square, London, W.C.1, price 7*s*. 6*d*. (or 5*s*. for students whose applications are endorsed by some person of suitable status).

Announcements

H.R.H. THE DUKE OF EDINBURGH will open the new wing of the Department of Engineering in the University of Cambridge on November 13.

SIR HARRY GARNER, chief scientist to the Ministry of Supply since 1949, is to retire early next year. He will be succeeded by Dr. O. H. Wansbrough-Jones, principal director of scientific research (defence) in the Ministry since January 1951 and formerly scientific adviser to the Army Council (see *Nature*, 157, 688; 1946).

AT the opening session on October 4 of the academic year at the University of Liège, the degree of doctor of medicine *honoris causa* was conferred on Prof. Réné Fabre, doyen of the Faculty of Pharmacy, University of Paris, and on Prof. D. Keilin, director of the Molteno Institute, University of Cambridge.

THE third meeting of the European Association of Exploration Geophysicists will be held in the Stadthalle, Corvinusplatz 2, Hannover, during December 4–5, the business meeting being held the previous evening. Twenty papers from various European countries will be presented as follows: nine on seismic, seven on gravity, one on magnetic, two on telluric and electrical, and one on radioactivity methods of prospecting. Further particulars can be obtained from the secretary/treasurer, Dr. B. Baars, 30 Carel van Bylandtlaan, The Hague, or from Dr. D. T. Germain-Jones, Kirklington Hall, Nr. Newark, Notts.

UNDER the provisions of the Fulbright Programme, travel grants are available to citizens of the United Kingdom and British Colonies to go to the United States for academic or educational purposes, provided that they have the financial support in dollars for the visit and are affiliated to an American institution of higher learning. The grants cover the cost of direct travel from the candidate's home to America and return, and are available during June 1, 1953–May 31, 1954. Applications must be submitted by March 16, 1953 (those travelling between June 1 and July 31) or June 15 (those travelling after August 1). Further information can be obtained from the United States Educational Commission in the United Kingdom, 55 Upper Brook Street, London, W.1.

IN a notice of the *Journal of Scientific Instruments* published in *Nature* of August 23, p. 298, it was remarked that: "When the *Journal* was started in 1923 it was the only periodical devoted to . . . scientific instruments". Mr. L. B. Tuckerman, of the National Bureau of Standards, Washington, D.C., points out that the first issue of the *Journal of the Optical Society of America and Review of Scientific Instruments* appeared in January 1922, and that the *Zeitschrift für Instrumentkunde* was a well-established journal by 1923, having been started in 1881.

THE new photoelectric absorptiometer referred to in *Nature* of October 25, p. 694, is manufactured and sold by the Hilger Division of Hilger and Watts, Ltd., 98 St. Pancras Way, Camden Road, London, N.W.1.

THIRD INTERNATIONAL SYMPOSIUM ON THE CHEMISTRY OF CEMENT

A SYMPOSIUM on the chemistry of cement, sponsored jointly by the Building Research Station of the Department of Scientific and Industrial Research and the Cement and Concrete Association, took place in London during September 15–20, the opening session being held in the Royal Institution and the others at the Royal Society of Arts. Sir Ben Lockspeiser, secretary of the Department of Scientific and Industrial Research, was president of the symposium, and Sir Francis Meynell, director of the Cement and Concrete Association, vice-president.

More than two hundred and fifty specially invited representatives attended, including more than a hundred from overseas, twenty-six countries in all being represented. In addition to the scientific meetings, visits to laboratories and factories and social events were arranged, all of which were well attended and appreciated.

In opening the symposium, Sir Ben Lockspeiser outlined the organization of research on cement and concrete in Great Britain and directed attention to the close co-operation which is maintained between Government institutions such as the Building Research Station and the Road Research Laboratory and those supported entirely by the industry, such as the Cement and Concrete Association and the individual laboratories maintained by the larger manufacturers. The annual production of concrete and concrete products in Great Britain amounts to a value of about £180,000,000, and of this sum only about one-fifth of 1 per cent is spent on research. This leaves room for further expansion of research on cement and its derivatives. Sir Francis Meynell, in a following address, brought out in greater detail the functions of the Cement and Concrete Association. It is supported by a levy on the tonnage of cement produced, and by the end of 1951 the grand total raised in this manner amounted to nearly 1¼ million pounds. Nearly £100,000 has been used for capital expenditure in the recently opened Research and Development Station of the Association at Wexham Springs. Other introductory addresses were given by Dr. R. H. Bogue, on behalf of Dr. A. A. Bates, vice-president of the United States Portland Cement Association, Prof. H. Lafuma, director of the Centre d'Études et de Recherches de l'Industrie des Liants Hydrauliques (France), and Prof. G. Wästlund, director of the Swedish Research Institute for Cement and Concrete. The final event of the opening session was a paper by P. Gooding and P. E. Halstead, on the early history of Portland cement in England.

The first of the technical sessions was devoted to studies of the constitution of Portland cement clinker. Papers were presented on tricalcium silicate (J. W. Jeffery, United Kingdom), dicalcium silicate (R. W. Nurse, United Kingdom), the interstitial phases (H. Insley, U.S.A.), the ferrite phase (G. L. Malquori and V. Cirilli, Italy), the alkali phases (T. F. Newkirk, U.S.A.), and tricalcium aluminate (F. Ordway, U.S.A.). Dr. R. H. Bogue, director of the Portland Cement Association Fellowship (U.S.A.), closed the session with a paper on "Studies on the Constitution of Portland Cement Clinker". It emerged from this series of papers that the crystal structures of the two main cementing agents, tricalcium silicate (Ca_3SiO_5) and dicalcium silicate (Ca_2SiO_4), are now known. Good approximations to the structures of tricalcium aluminate ($Ca_3Al_2O_6$) and the ferrite phase have been found. All these minerals take up minor oxides in solid solution, the composition of the ferrite phase being particularly variable, and some are further complicated by polymorphism. The information derived from crystal-structure studies has supplemented that obtained from phase-rule studies and from microscopic and X-ray examination of cement clinker. Methods of dealing with systems of four to six components were discussed by Dr. Bogue, and advances in technique, such as the high-temperature centrifuge and methods of growing single crystals for X-ray structure analysis, were described.

In the session devoted to the setting and hardening of Portland cement, papers were presented by Prof. J. D. Bernal (United Kingdom), H. H. Steinour (U.S.A.), G. L. Kalousek (U.S.A.), F. E. Jones (United Kingdom) and Prof. T. Thorvaldson (Canada). Much progress was reported in the chemistry and crystallography of the hydrated calcium silicates. The unit-cell dimensions have been determined for ten of the natural or artificial hydrated calcium silicates, which appear to form two groups, having respectively a fibrous or non-fibrous character. The fibrous group is characterized by a short fibre repeat unit of 3·65 A., which may imply the existence of silicate tetrahedra joined by hydrogen bonds, or may arise from columns of Ca—Si—O linkages. $(SiO_3OH)^{3-}$ ions have been shown to exist in afwillite. At normal temperatures two closely related calcium silicate hydrates are formed in the system $CaO—SiO_2—H_2O$, both belonging to the fibrous group and also having a layer structure, the spacing of the layer varying with the state of hydration between 9 and 14 A. This behaviour is reminiscent of certain clay minerals, and may be related to the shrinkage properties of concrete. The method of differential thermal analysis has been applied to the study of the hydrated calcium silicates, and many of the advances reported were made possible by new techniques in X-ray crystallography.

Some divergence of opinion developed regarding the constitution of set cement, the results of differential thermal analysis being interpreted as showing the existence of a single phase, whereas limited X-ray data seemed to show the independent existence in the set mass of calcium silicate and aluminate hydrates. The two methods do, however, give consistent results when applied to the study of cement cured at high temperature and pressure. Although steam treatment is commonly applied as a method of accelerating the development of strength in concrete products, it has long been known that under certain conditions the expected gain in strength may not materialize. This was shown to be related to the formation under transient conditions of a calcium silicate hydrate of the non-fibrous group.

An interesting development in the study of chemical attack on concrete is the use of radioactive sulphur as a tracer to determine the rate of diffusion of the sulphate ion in cement pastes and mortars.

The Second International Symposium (Stockholm, 1938) dealt only with Portland and high-alumina cements; but the scope of the present meeting was extended to include a session on special cements.

Papers were read on high alumina cement (T. W. Parker, United Kingdom), slag cements (F. Keil, Germany), expansive cements (Prof. H. Lafuma, France), oil-well cement (W. C. Hansen, U.S.A.) and masonry cement (C. E. Wuerpel, U.S.A.).

The constitution of high-alumina cement is complicated by the division of its fairly high iron content between the ferrous and ferric state. Theories of constitution have, in the past, been based mostly on the results of petrographic examination, since phase-rule studies have not been of great value. At the recent meeting, it was shown that if MgO is used as a 'model substance' for FeO, phase data in the system $CaO—MgO—Al_2O_3—SiO_2$ can be applied to this problem. Thus the blue pleochroic mineral described by Sundius and others has been shown to have the composition $6CaO.4Al_2O_3.FeO.SiO_2$. In identifying the calcium ferrites and alumino-ferrites, measurement of reflecting power of the microscopic grains has been found useful.

The principal constituent of slag cements is a glass formed by the rapid quenching in water of molten blast-furnace slag. Such glasses vary widely in their reactivity as cements, and many attempts have been made to relate this activity to chemical composition. Work on artificial glasses containing only a few components was described, and also preliminary attempts to elucidate their structure by chemical means. A number of useful empirical tests for the quality of granulated slag were discussed.

The deliberate production of a controlled expansion is one method of compensating the shrinkage which accompanies the drying of normal cements. For certain applications, such as patching, underpinning and post-stressing, a larger expansion can be produced if necessary. The method employed is to bring about the formation of calcium sulphoaluminate in the set mass; this reaction is the principal cause of the disintegration of concrete in sulphatic waters; but in the present application the expansion is kept under careful control.

Oil-well cements are required to set at considerable depths below the ground under conditions of high temperature and pressure; but the setting time must be long enough for the cement slurry to be pumped down to the required depth. In the paper presented to the symposium, the various organic substances used for regulating the set were classified and it was suggested that HO—C—H groups are particularly effective in retarding the action of water on cement.

For use in masonry jointing or as a rendering, ordinary cement requires to be diluted with lime, limestone or fine sand, to reduce the formation of shrinkage cracks, and to improve the working properties of the mortar. Air-entraining agents may also be added. A modern development is to market the accurately proportioned mixture as masonry cement. Various problems arise in testing such cements, involving a knowledge of the rheological properties of stiff and semi-plastic pastes.

In the final session, the applications of research in cement manufacture were discussed in papers by H. Gygi (Switzerland) and T. Heilmann (Denmark), while A. R. Collins (United Kingdom) and M. A. Swayze (U.S.A.) presented papers on problems in the utilization of cement.

The closing address was given by Dr. F. M. Lea, director of building research, Department of Scientific and Industrial Research, who surveyed the work of the symposium and suggested lines along which future research might be developed. He referred to the great advances made since the last symposium in the application of X-ray analysis to cement research. One of the most baffling problems in this field has been the determination of the state of the water held in set cement. By means of X-ray structure analysis, it has been shown that some of the water chemically combined can be present as hydroxyl groups and some as molecular water. There must be a relationship between the expanding lattice of the hydrated silicates and shrinkage and moisture movement of concrete. The picture that is emerging as a result of this work and of the physical studies made on cement pastes using the adsorption isotherm technique is much more satisfactory than the earlier theories based solely on capillary phenomena and the Kelvin equation.

The combination of electron microscopy with electron diffraction is proving in this, as in other fields, a powerful research tool, and the use of ultrasonic energy for dispersing material and hastening chemical reaction is of great interest and may possibly have practical applications.

As a result of the research already done, the civil engineer is now presented with a choice of cements eminently suited to particular applications. As old problems are solved, however, new ones arise, and there is a constant need for a background of research in an industry so important as that of cement manufacture.

The proceedings of the Symposium, including the written and spoken discussion, will be published. Inquiries should be made to the Organizing Secretary, P. Gooding, Cement and Concrete Association, 52 Grosvenor Gardens, London, S.W.1. R. W. Nurse

---

INTERNATIONAL ASTRONOMICAL UNION

The eighth General Assembly of the International Astronomical Union was held in Rome during September 3–13, on the invitation of the Consiglio Nazionale delle Ricerche. The inaugural ceremony took place in the Hall of Orazi and Curiazi in the Campidoglio, when the Mayor of Rome, the president of the Consiglio Nazionale delle Ricerche, Prof. Gustavo Colonnetti, and the Minister of Education welcomed the Congress, and the president of the Union, Prof. Bertil Lindblad, replied. More than four hundred delegates from thirty-six countries were present. After the opening session of the General Assembly, the Union resolved itself into a number of small groups: thirty-nine commissions of the Union covering all branches of astronomy met either separately for their special work or jointly for discussions of common interest. In addition, two Joint Commissions of the International Council of Scientific Unions—Spectroscopy and Solar and Terrestrial Relationships—took the opportunity of the gathering to hold meetings in Rome at the same time. Further, three symposia were organized, each for a full day. These were on "Stellar Evolution", on "The Astrometry of Faint Stars" and on "Instruments".

The following took part in the first symposium: V. A. Ambartsumian, O. Struve, B. Lindblad, W. Baade, E. Kukarkin, L. Gratton, F. Hoyle, A. Severny, G. A. Shajn, C. Fehrenbach, V. G. Fessenkov, E. Schatzmann, G. P. Kuiper, M. Schwarzschild,

T. Gold, H. Alfvén, R. A. Lyttleton and D. Martynov. The papers of Shajn and Fessenkov were read for them in their absence. The discussion, as may be judged by the names of those taking part, was lively and at times argument was intense; naturally, no decisions were reached, but a most stimulating meeting was held. The importance of Baade's two stellar populations came prominently into view. The chairmen were H. Bondi and O. Struve.

In the second symposium, which was concerned with the positions and motions of faint stars, the chairmen were J. Jackson and A. A. Nemiro. The subject-matter was less controversial, but perhaps more fundamental, than in the case of the first symposium, and the speakers or contributors of papers included M. S. Zverev, A. Blaauw, A. N. Deutsch, A. Kopff, J. Larink, J. H. Oort, E. W. Rybka, S. Vasilevskis, A. N. Vyssotsky, D. Brouwer and R. H. Stoy. In the third symposium E. H. Linfoot, A. Couder, A. Lallemand and I. S. Bowen presented papers on various telescopes and auxiliary apparatus.

Several of the meetings of groups of commissions must be mentioned. The Commissions on Ephemerides, Astronomical Constants, Celestial Mechanics, the Moon, Minor Planets, Comets and Satellites held a joint meeting at which the recommendations were adopted which had been made to the Union by the Paris conference, held in 1950, on the fundamental constants of astronomy. A whole day was devoted to a discussion of the spectra of variable stars at a joint meeting of the Commissions on Variable Stars and Stellar Spectra—more than thirty papers were presented. A joint meeting of the Commissions on Radio-astronomy, Interstellar Matter and Stellar Statistics produced, perhaps, the high lights of the meeting—Oort's account of the possibilities of exploring the dark arms in the Milky Way spiral structure through the use of the 21-cm. line due to atomic hydrogen, and Baade's account of the discovery of rings and wisps of nebulosity surrounding the positions of radio stars located by the observers at Cambridge and Manchester.

During the meeting, visits were paid to the Observatories at Castel Gandolfo and Monte Mario. On the former occasion, His Holiness Pope Pius XII addressed the Union on the progress achieved by astronomy and astrophysics in the past fifty years, and afterwards met individual members and spoke with them on their work.

At the closing session of the Union, a number of recommendations from the Commissions were adopted. Among others, mention must be made of the folowing: an appeal for observations of the transit of Mercury across the sun's disk in November 1953; an amendment of Brown's Tables of the Moon by removing the empirical term and applying a correction to the mean longitude; an appeal for further work in the southern hemisphere in the field of fundamental meridian astronomy, catalogues of faint tars, and an extension of the Lick sky survey; another appeal for systematic measurements of the general magnetic field of the sun; a suggestion for a oint commission with the Unions of Geodesy and Geophysics and of Radio-Sciences to arrange, possibly n connexion with a proposed International Polar (or Geophysical) Year in 1957–58, for a third set of eterminations of an accurate network of world ongitude; and a general adoption of the three-letter omenclature for constellations. Financial recommendations approved by the Finance Committee and dopted included a number of regular items and, in addition, a grant for the Astronomical News Letters which summarize work published exclusively in Russian; a grant to Meudon Observatory to put into operation the photo-electric photometer of the late Bernard Lyot, for measuring the intensity of solar coronal spectral lines; a grant to P. Swings for the publication of a photographic atlas of typical spectra of comets; and a grant to facilitate the exchange of astronomers between countries.

Invitations for the next General Assembly of the Union had been received from Eire and Poland. A vote by countries was in favour of accepting the invitation from the Dublin Institute for Advanced Studies, and the next General Assembly will be held in Dublin in 1955. The Bureau for the next three years was elected as follows: *President*, O. Struve (U.S.A.); *Vice-Presidents*, V. A. Ambartsumian (U.S.S.R.), A. Couder (France), E. Rybka (Poland), P. Swings (Belgium) and R. v. d. R. Woolley (Australia); *General Secretary*, P. Th. Oosterhoff (Netherlands). The retiring president and secretary, B. Lindblad (Sweden) and B. Stromgren (Denmark and U.S.A.), are *ex officio* members.

The above account indicates clearly the crowded nature of the activities of a very successful meeting. Although the symposia and group meetings were most successful and added greatly to the interest of the meeting, there were signs in several quarters of a tendency to crowd out the administrative organizational work of the separate commissions. This tendency must be watched carefully, as such work is the real fundamental basis of the Union's continued success. No account of the meeting could be regarded as complete without reference to the most generous hospitality received in Rome from the Mayor of Rome and from the Consiglio Nazionale delle Ricerche, who placed every facility at the disposal of the Union.

F. J. M. STRATTON

THE BRITISH PHARMACEUTICAL CONFERENCE, 1952

THE eighty-ninth British Pharmaceutical Conference was opened at Nottingham on September 1 and the attendance exceeded five hundred. The chairman, Mr. H. B. Mackie, approached the subject of pharmaceutical education with originality when he entitled his address: "An Education for a Pharmacist". He pictured the pharmacist as a professional man, comprehending the scientific basis of drugs and drug action, able to evaluate critically the products he handles and competent to advise physicians concerning drugs and their uses.

The early education of the future pharmacist, Mr. Mackie said, should be as broadly based as possible, designed to discover aptitudes and latent potentialities and should seldom degenerate into formalized, didactic instruction. Latin might be restored to its original place, for young people lacking Latin have a hard road to travel to be completely literate. The test of a successful early education is not the amount of knowledge that a pupil takes away from school but his appetite to know and capacity to learn.

Of professional studies, there is little to be said concerning pharmaceutical chemistry—now fairly clearly delimited. Pharmacology and pharmacognosy used in the broadest sense mean the same thing, 'knowledge about drugs', both terms having now assumed an acquired meaning. Pharmacology is important, since it provides a link in the chain of knowledge between pharmacy and medicine. A modern education for a pharmacist must strengthen the link. The changing and enlarging field of therapeutics confronting the physician makes it imperative that he have assistance in finding his way through the labyrinth of complex, controversial materials. The pharmacist should be so trained as to be a source of authentic, unprejudiced information and able to inform the public as to the merits of new therapeutic agents. Probably all would agree that any course of applied science should provide information, useful to the student in solving problems of to-day and to-morrow, while teaching principles in preference to communicating isolated facts. Facts are quickly forgotten and are found in hand-books. Understanding is more difficult to acquire, but once acquired becomes an integral part of the student's mind.

The use of drugs has a very long history; but pharmacognosy as a science dates from the beginning of the nineteenth century. Despite increased chemical knowledge about natural products, there has been little influence upon the teaching of pharmacognosy. The subject could be usefully integrated with pharmacology. Although doubts have been expressed about the necessity of pharmacognosy for the practising pharmacist, it is pharmacy's specific and peculiar contribution to the cause of science. It behoves us to esteem it well.

Galenical pharmacy enables us, Mr. Mackie pointed out, to present trains of thought and methods of scientific manipulation, which as yet lie outside the domain of equations and formulæ. Terms such as 'tincture' and 'syrup' apply to a complex association of materials derived from vegetable structures, and processes involved in their preparation date to the beginning of man's historical record. Galenical pharmacy is and always has been based on colloidal complications. As the normal structure and juices of most or all plants are colloidal, the study of pharmacy as applied to natural substances is that of colloidal research and colloidal manipulation. Accepting that non-crystalline substances compose the major part of plant tissues, it becomes the pharmacist's duty to disentangle these complicated structures, providing a product not having undergone fundamental re-arrangement.

There is no 'alkahest', no universal solvent, as was dreamt of by Paracelsus. The most promising neutral liquids for extracting natural colloidal groups are listed by Uri Lloyd. These solvents may virtually exhaust most plant contents. A saturate is not an ultimate, but may be complex and require subdivision, giving more closely related substances. Such manipulation individualizes colloidal plant structures to a degree of pharmaceutical satisfaction, though not absolute chemical perfection. The use of a neutral liquid as an excluder is exemplified in ox-bile and the piecemeal separation of certain opium alkaloids; then reassembly produces well-known injectable products. There appears practically no limit to the production of medicaments which evoke the precise therapeutic response desired, plus the synergistic effect that frequently accompanies this, while free from inhibiting or damaging reaction. Colloidal scales possessing all the properties of the original drug may be produced. A new field has been introduced by the discovery of the alkaloidal affinities of hydrous aluminium silicate, though it is not yet certain if it will enable us to obtain plant substances in a purified and active form.

In the therapeutic application of a substance its condition is most important; for example, the superiority of finely divided mercury. The alkaloidal strength of a nux vomica galenical may be increased by adding strychnine, but has the quality improved?

The attempt to achieve standardization by a single dominating constituent is but a struggle towards a pharmaceutical standard of excellence in which therapeutic quality should be the ideal and which for the moment should be stressed in our scheme of training. It is fanciful to believe that there is some analogy between elaborately processed 'foods' and the substitution of synthetic chemicals in medicine for naturally occurring substances. The future pharmacist will not be chiefly a purveyor of tablets, and it may be true to-day as when written in medieval times that "Contra malum mortis non est medicamen in hortis".

Mr. Mackie completed his address by reminding his fellow-teachers that some of the most important men in history have been teachers. Many of the biggest advances in civilization have been the chief work, not of politicians or inventors, not even of artists, but of teachers. We have Ruskin's assurance that pay alone never made a better soldier or a teacher. We are servants of reality; our responsibility is to the young and through them to the future.

Among the scientific papers read and discussed at the Conference, there were several which reflected the tone of the chairman's address. Factors influencing the separation of hyoscine and hyoscyamine by elution development of a chromatographic column had been studied and a simple assay described. Another paper was concerned with the detection of common medicinal alkaloids by the chromatographic method. Much work was reported on the assay of *Digitalis* glycosides. One group of workers had investigated the assay of mixed chloroform-soluble glycosides, while others dealt with the colorimetric estimation of digitoxin and compared the method with biological assay.

Assay methods were, in fact, a prominent feature of the papers read. The polarographic estimation of riboflavine was found to be more reliable than the simple colorimetric method and more rapid than other methods used. The available methods for the determination of ascaridole were reviewed and a possible polarographic method examined. The use of emission spectrography in pharmaceutical analysis was reported upon, and the methods outlined showed a considerable saving of time over normal chemical methods. A useful contribution was made to the evaluation of surface-active agents, based on the measurement of stability of the emulsions yielded. Two workers indicated that a small lymphocyte count is a more accurate method of pyrogen assay than temperature measurement.

Studies on tuberculostatic compounds reflected the vitality of pharmaceutical research. Papers dealt with methods of assaying *iso*-nicotinic acid hydrazide and the more general pharmacology of *p*-aminosalicylic acid.

Antibiotics featured prominently in the discussions of the Conference, and it was reported in one paper that the pharmacodynamical groups present in the chloramphenol series fall into two categories, namely, specific and relatively non-specific. Recent developments in the pharmacy of antibiotics were dealt with in a symposium session which covered aspects of general and hospital practice. A contribution to the latter session gave a more widespread picture of the subject and illustrated the remarkable expansion of knowledge achieved since the general discussion on penicillin at the 1946 Conference.

Other developments in the field of pharmaceutics included the successful use of infra-red radiation for drying a wide variety of products. Bacterial survival in systems of low moisture content was further reported upon, namely, the effects of increasing moisture content on heat resistance, viability and growth of *B. subtilis* spores. The determination of quality of surgical dressings had been further investigated, on this occasion being concerned with their water retention.

S. B. Challen

FISHERIES RESEARCH UNIT OF THE UNIVERSITY OF HONG KONG

THE need for a Fisheries Research Station in Hong Kong has long been realized; but the various plans for one which have been put forward from time to time have for various reasons been found impracticable. However, a satisfactory scheme was recently worked out by the University of Hong Kong in conjunction with the local Government, and a Fisheries Research Unit commenced work recently in the University's Department of Biology. The University has provided approximately a thousand square feet of laboratory accommodation for the Unit, and the director is reader in marine biology on the University's staff. The association between the Unit and the Department of Biology esembles that existing between various agricultural esearch units which are attached to a number of universities in Great Britain, for example, the Bureau of Animal Population and the Department of Zoology n the University of Oxford.

The director, Mr. Alan Tubb, who was formerly director of fisheries in the Colony of North Borneo, will take up his duties in April next year; meanwhile, Prof. D. Barker, professor of zoology and head of the Department of Biology in the University, is acting irector. The director will be assisted by a chief scientific officer and three assistant scientific officers; so far, two assistants have been engaged. The rest f the staff establishment consists of a laboratory teward and attendants, and the skipper and crew f a research vessel at present under construction. The laboratory accommodation includes marine quaria supplied with running sea-water, and a aboratory suitable for chemical and biological work. here is a considerable library of books and journals n fisheries research, and the Unit has access to the University's scientific library. Provision has been made for equipping the Unit's laboratory with the ppropriate research facilities and apparatus. The cost of establishing the Unit is being met out of olonial Development and Welfare funds, while ecurrent expenditure is being met by the local overnment; in each case the government conibution is by means of block grants made over to he University for its administration.

The research vessel is a 66-ft. diesel-power ter trawler. The keel is now being laid a e should be in commission by the summer o 953. She will be equipped with a laboratory, ech sounder, radio telephone and wireless telegraphy, bottom sampler, bathythermograph, and various other apparatus required for oceanographical work. The vessel will work in waters up to a hundred miles distant from Hong Kong, and the longest trips will be of from seven to ten days duration.

From the point of view of marine research, Hong Kong is very favourably situated, being at the extreme south-east corner of Asia almost at the junction of temperate and tropical waters and within easy reach of ocean and estuarine fishing grounds. The Fisheries Research Unit is the most easterly of a chain of Commonwealth fisheries research stations, and its researches and findings will not only be correlated with those of Ceylon, Malaya and India, but will also be of value to the Dominions of Canada and Australia and to other countries which border on the Pacific Ocean or the China Sea. It is expected that the research carried out by the Unit will lead to improvements of catch in the immediate neighbourhood of Hong Kong and will contribute substantially to general fisheries research in the Indo-Pacific region. Under the auspices of the Indo-Pacific Fisheries Council, the Unit will pool its results and collaborate with similar stations in the Philippines, North Borneo, French Indo-China and Malaya in research projects relating to the China Sea. Among other problems the Unit will aim at undertaking the following research: survey the existing fishing grounds around Hong Kong, map them, and determine their species population and production; survey the sea-bottom, salinity and plankton in local waters; study ocean currents and the effect of such currents and prevailing winds on the movement of fish, with the possibility of discovering new fishing grounds; determine the influence of the Pearl River on the fishing around Hong Kong; study factors influencing the yield of catch in the local fishing grounds with the view of forecasting production; investigate the movement and feeding habits of fish, and, wherever possible, locate spawning grounds, etc., with the aim of trying to initiate control; make studies in relation to the extension and improvement of salt, brackish and freshwater fish-pond culture.

UNESCO INSTITUTE FOR EDUCATION, HAMBURG

UNESCO has recently sponsored an unusually interesting experiment in West Germany, on a smaller scale than those activities with which Unesco is popularly associated. The experiment consists of the establishment of three Institutes, each of which began work during 1952. One is for Social Sciences at Cologne; one for Youth, at Munich; and one fo Education, in Hamburg.

These Institutes are remarkable in two respec First, each has an international governing bo consisting of seven non-German and six Germ members, the funds of which are derived not from general Unesco budget but in response to an ap by the Director-General to individual nati Secondly, the Federal Republic of Germany agreed [illegible] the establishment w [illegible] amounts to the Institutes are to be found India and the Philippines; and the United Kingdom is not to be found among the principal contributors, France, Germany and the United States.

With regard to the Institute of Education at Hamburg, the objects are briefly: (1) to foster international study of educational problems (particularly to enable German educators to meet educators from other countries); (2) to carry out research into educational aims and methods; and (3) to participate in action undertaken by Unesco in its campaign for the maintenance of peace and in its programme of education for international understanding.

The Governing Board determines policy from time to time and is responsible for framing an annual budget. The Board consists of representatives of Germany (six), Canada, Denmark, France, Italy, Switzerland, the United Kingdom and the United States of America (one each), together with a representative of the Director-General of Unesco. From among the members of the Board, a Standing Committee of five has been appointed, again with a marginal majority of non-German members.

The Governing Board decided that the first item on the programme of the Institute should be a seminar on "Adult Education as a Means of Developing and Strengthening Social and Political Responsibility". This seminar opened on September 8 and continued for one week. Thirty-five participants from fourteen countries (including three from England) were the guests of the Institute. The physical atmosphere of the Institute provided assurance of a favourable meeting place. The introductory remarks of the director of the Institute, Prof. Walther Merck, and of the chairman of the Governing Board, Prof. J. Novrup (but in his capacity as an ordinary participant) led the seminar along the road of realistic discussion of some of the problems of adult education. The five groups into which the members divided (two English-speaking, two German and one French—but with a wide distribution of nationalities) discussed aspects of political responsibility, social responsibility and special methods in adult education. It was generally agreed that nothing really new had emerged, or indeed could be expected to emerge, but that for the first time the issue of political responsibility had been squarely faced. A full report will be published later in English, French and German.

Anyone attending the Institute's social evening, with cold supper and wines served in the Institute House, and joining the subsequent gathering in the library, would have found it difficult to believe that such a diversity of nations could behave and indeed think and act with such bon-accord, despite difficulties of language.

The Institute received many valuable suggestions for further action, and these are now being examined to find out how far they can be implemented, and whether some of them can be pursued in co-operation with the Youth and Social Sciences Institutes.

The second major item on the Institute's pro- [illegible] seminar on "The Factors of Pre- [illegible] ch influence the Development [illegible] able to participate in a [illegible] e of this seminar has [illegible] ill be held in the [illegible]

HUGH MILLER, 1802-56

COMMEMORATION AT CROMARTY

By SIR EDWARD BAILEY, F.R.S.

COMPARATIVELY few now remember the stir attending the centenary of Hugh Miller's birthday, celebrated in 1902. Some 1,500 pilgrims from far and near assembled under the great column and statue which already commemorated Cromarty's most distinguished son. Sir Archibald Geikie was that day chief among a dozen speakers, including Principal Rainy, of the United Free Church, Prof. Clarke, of Albany, U.S.A., Dr. John Horne, of the Geological Survey, and Sir James Grant, president of the Royal Society of Canada. Geikie gave of his best in love and gratitude to the memory of the man who had introduced him, and many others of his generation, to the wonderland of geology. In doing so he remarked, a little pathetically, that he found himself the last survivor among geologists who could lay claim to intimate friendship with the erstwhile stonemason. Fortunately, his beautiful address is fully reported in *Nature* (66, 426, 1902), while the ceremony as a whole is detailed in a valuable booklet entitled "The Centenary of Hugh Miller" (Glasgow, 1902).

Carnegie was among those present at the centenary gathering, and shortly afterwards he generously presented Cromarty with a Hugh Miller Library and Institute—a further fitting memorial. Then, in 1938, the National Trust of Scotland, which meanwhile had come into existence, took over from the Town Council the cottage where Hugh Miller had been born, already functioning as a shrine. The occasion was marked in *Nature* (142, 696; 1938) by an appreciation of Hugh Miller's work.

On October 14 of the present year, on the invitation of the Earl of Wemyss, chairman of the National Trust, a small gathering of about fifty met in the paved courtyard of Hugh Miller's cottage to celebrate the hundred and fiftieth anniversary of the great man's birth. After the chairman had explained the Trust's need for additional memberships and subscriptions to carry on its vitally important tasks of conservation, he asked Sir John Erskine, general manager of the Commercial Bank of Scotland, to recall a significant episode in Hugh Miller's career. Sir John reminded us how, after fifteen years as stone-mason, Hugh Miller, in 1834, accepted an offer of the accountantship of the Commercial Bank's agency at Cromarty; and how he held this post until, at the beginning of 1840, he agreed to edit *The Witness*, a militant newspaper launched to represent the views of an important section of the Presbyterian Church of Scotland. Sir John cited contemporary evidence of Hugh Miller's speedy adaptation of himself to a totally new style of endeavour, which brought him not only increase of money—very welcome to a man in love—but also increase of opportunity for study and writing.

Subsequent speakers were the Rev. J. H. Baxter (University of St. Andrews) and the Rev. John Macleod (University of Aberdeen). Both stressed the intensely religious outlook of Hugh Miller and his extraordinary (and also successful) introduction of ological discovery into the pages of *The Witness* om the very start of his editorship.

The anniversary meeting was blessed throughout ith perfect weather. An additional delightful feature was the presence of two great-grandchildren of Hugh Miller (Brigadier A. A. Middleton and his sister), along with two great-great-grandchildren and one great-great-great-grandchild—the latter, Louisa Gordon, aged six. Brigadier Middleton's father, Sir Thomas Middleton—a mere grandson—had been one of the speakers at the centenary fifty years ago; now Louisa Gordon was invited by Lord Wemyss to head the roll of attendance with her signature.

COBALT IN THE NUTRITION OF RUMINANTS*

Response of Cobalt-deficient Sheep to Massive Doses of Vitamin B_{12}

We now have unequivocal evidence that the deficiency-syndrome suffered by sheep grazed on cobalt-deficient pasture is, in fact, the result of vitamin B_{12} deficiency.

Experiments[1] conducted here in 1943–44, which showed clearly that, to be effective for the prevention or for the cure of the malady, cobalt must be administered *per os*, focused attention on the nutritional importance of cobalt for the development of some at least of the mixed population of organisms which normally inhabit the rumen, and indicated that cobalt might exert its activity, primarily, by favouring the proliferation of organisms responsible for the production of accessory food factors essential for the animal.

The fact that a profound macrocytic anæmia is a feature of the terminal stages of the cobalt-deficiency syndrome led us, early in our studies, to examine the effects of dosing with liver extracts, and much later, when small supplies of vitamin B_{12} became available, the effects of administration of the pure, cobalt-containing vitamin. The doses used in these earlier experiments were of similar order to those employed for depot therapy in the treatment of Addisonian pernicious anæmia (that is, 15–30 U.S.P. injectable units a week: the U.S.P. unit of liver extract contains approximately 1 μgm. vitamin B_{12}). In a series of experiments which would have enabled small effects to be measured, no significant change in the progress of the syndrome was observed to supervene on treatment with these amounts of liver extract or of vitamin B_{12}, irrespective of whether the dose was administered *per os* or parenterally.

More recently, Becker and Smith[2], who had identical experience with similar doses, reported that injection of much larger quantities of liver extract (15 U.S.P. units a day) into cobalt-deficient lambs elicited responses of the same order of magnitude as those brought about by administering adequate cobalt *per os*. These authors mentioned in an addendum to their paper that "larger amounts of vitamin B_{12} do result in a positive response in cobalt-deficient lambs", and, later, supporting evidence was published[3].

The first report led us to study the effectiveness of parenteral injection of relatively large amounts of vitamin B_{12} (equivalent to 300 μgm. vitamin B_{12} a week) into experimental sheep which had developed cobalt-deficiency while grazing on cobalt-deficient pastures, and which had failed to benefit from intramuscular injection of the equivalent of 15 μgm. vitamin B_{12} a week.

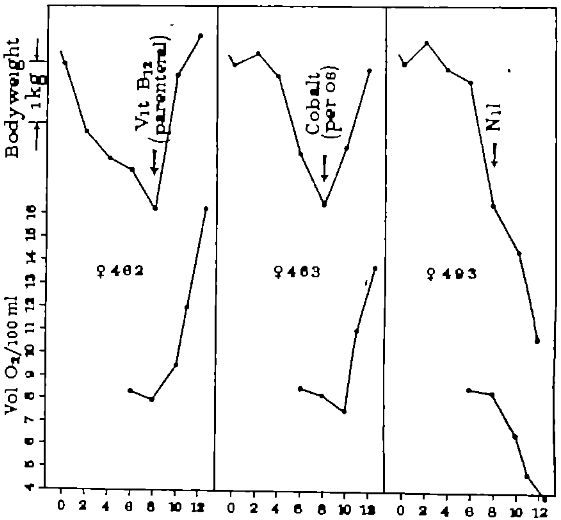

Fig. 1. Effect of treatment with cobalt and with vitamin B_{12} on the body-weight and oxygen-carrying capacity of the blood of ewes in an advanced stage of cobalt deficiency

The responses reported in Fig. 1 are typical. This group of three young merino ewes was one of a series drawn from an experimental flock that had grazed for approximately a year on frankly cobalt-deficient pastures, and which had not previously been treated with cobalt. All were in an advanced stage of cobalt-deficiency. The first criterion adopted for the selection of the animals into groups was the degree of anæmia —the oxygen-carrying capacity of the bloods of the animals in this particular group was close to 8 vol. oxygen per 100 ml. at the period when they were selected for treatment. The animals were of similar body-weight (c. 20 kgm.). At the point indicated, No. 462 was treated with 300 μgm. vitamin B_{12} a week, injected into the gluteal muscles in doses of 100 μgm. thrice weekly; No. 463 was treated with the equivalent of 7 mgm. cobalt a week administered *per os* thrice weekly at similar intervals; No. 493 was untreated and served as a control. The effects of the treatment are obvious. The slight lag in the response of No. 463 was typical of many but not all of the animals which received cobalt.

These observations, together with others from more intensive studies[4] of cobalt-deficient sheep confined in metabolism cages under laboratory conditions, leave little doubt that the syndrome of cobalt-deficiency in ruminants is the result of a shortage of vitamin B_{12}, and point to the probability that ruminants require much more of this vitamin than do other animals. Normally, when the cobalt concentration of the ingesta imposes no limit to the proliferation of organisms responsible for the synthesis of vitamin B_{12} in the rumen, the amount produced there is large (see footnote 5 for references).

A full account of these experiments will be published elsewhere.

of Cobalt-deficiency in Sheep by Injection of Vitamin B_{12}

ES of experiments with merino ewes confined abolism cages and fed on cobalt-deficient has proved, *inter alia*, that vitamin B_{12}, iced parenterally in relatively massive amounts, revent the development of cobalt-deficiency oms and will spectacularly restore normal to sheep which have developed the malady. ndings imply that, in the nutrition of ruminants, functions merely to stimulate the proliferation se micro-organisms in the rumen which produce obalt-containing vitamin B_{12}; the activity of icro-organisms responsible for the fermentation rbohydrate in the rumen remains unimpaired the cobalt concentration of the fodder is reduced level which induces the profound deficiency-syndrome in the animal, as critical balance experiments have proved that the digestibility of the rations remains unaltered in these circumstances. The failure of appetite, which is the first symptom to appear, and which is progressive, is thus the result of a metabolic defect and not of a reduced capacity of the animal to digest and absorb its foodstuffs.

In these experiments the ration offered each day was comprised of 1 kgm. of cobalt-deficient wheat hay and 50 gm. of washed wheat-gluten: it provided 4,100 kcal. (gross) of combustible energy, of which between 40 and 42 per cent was voided in the fæces; it provided the protein equivalent of 18·3 gm. nitrogen, of which 5·9 gm. nitrogen appeared in the fæces; and, as the chaff contained 0·025 μgm. cobalt per gm. and the gluten rather less, it provided < 25 μgm. cobalt a day, which is less than one-third of the minimum requirement estimated from experiments with sheep on cobalt-deficient pastures[1]. When supplemented with cobalt, these rations maintain mature sheep (40–45 kgm.) in positive energy balance and in excellent health.

After being taken from normal pastures and confined to these rations, all the ten mature ewes which comprised the experimental animals referred to here increased gradually in weight for a period which, in some, extended for several months before their tissues became depleted to a degree which no longer allowed the animal to deal effectively with the whole of its rations; appetite then began to fail and eventually the syndrome progressed steadily in all the animals that were untreated.

The performance of the three ewes recorded in Fig. 2 is typical of the individuals which were the first to develop deficiency symptoms. The responses of No. 5009 to a supplement of 1 mgm. cobalt a day, *per os*, and of No. 7019 to 50 μgm. of vitamin B_{12} per day, injected intramuscularly, are virtually identical, and leave little doubt that the cobalt-deficiency syndrome is the consequence of a metabolic defect resulting from a deficiency of vitamin B_{12}.

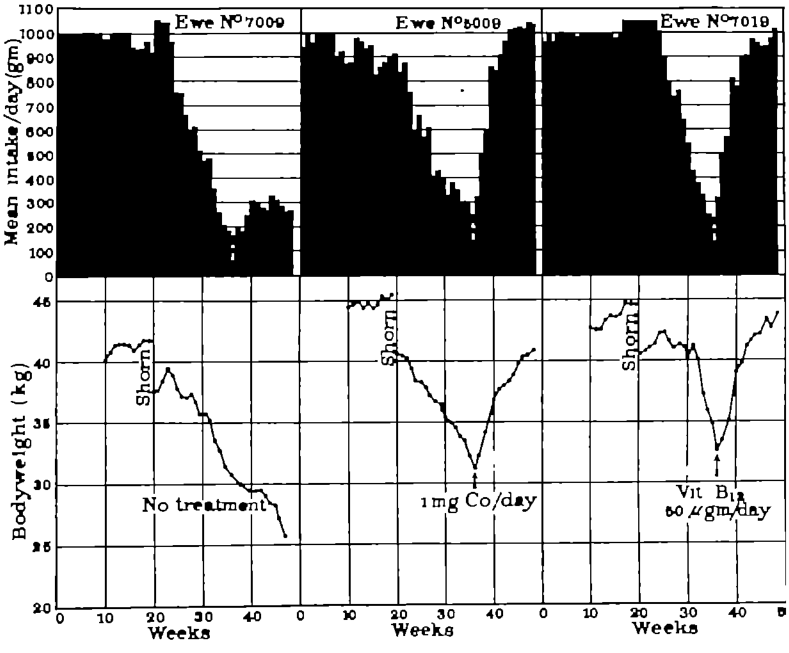

Fig. 2. Effect of treatment with cobalt or with vitamin B_{12} on the progressive failure of appetite and consequent loss of weight of sheep confined on rations short of cobalt

Of another group of three ewes, which after thirty-five weeks under identical conditions had not become depleted to the stage at which appetite begins to fail, one was treated with 1 mgm. cobalt a day *per os*, one with intramuscular injections of 50 μgm. vitamin B_{12} a day, and one was left untreated. The overall digestibility of the rations, and the vitamin B_{12} activity of the excreta, were determined in two 14-day periods, one immediately prior to treatment and one which began 14 days subsequent to the day on which treatment was started. Cobalt administered *per os* to No. 5012 increased the vitamin B_{12} activity in its fæces from 490 to 3,700 μgm. vitamin B_{12} (equiv.) per day as assessed by the *Escherichia coli* assay and from 245 to 720 μgm. vitamin B_{12} (equiv.) a day by the *Lactobacillus leichmannii* assay; whereas vitamin B_{12} administered to No. 9072 effected no significant change, the mean activities of the fæces passed in the pre- and post-treatment periods being 590 and 520 μgm. vitamin B_{12} (equiv.) a day (*E. coli*) and 250 and 280 μgm. vitamin B_{12} (equiv.) a day (*L. leichmannii*) respectively. The appetite of the untreated ewe, No. 9090, began to fail during the second collection period; at that juncture the mean vitamin B_{12} activity of its fæces was 400 and 270 μgm. vitamin B_{12} (equiv.) a day, as estimated by the respective methods.

As the treated animals in this group consumed the whole of their rations during both periods, the overall digestibility of cellulose and the quota of the combustible energy in the fodder which was excreted in the fæces could be estimated precisely. Neither cobalt (*per os*) nor vitamin B_{12} (parenteral) effected any change in the overall digestibility of the fodder, although a considerable alteration in the nature of the microbial population of the intestinal tract of the animal which received a supplement of cobalt is implied by the increase in the vitamin B_{12}-activity of its fæces. Similar balances were conducted on the other three animals mentioned above. The vitamin B_{12} activity of their excreta is discussed by our colleagues, Dawbarn *et al.*[2], who were responsible also for the microbiological assays reported here.

In all, these findings are in complete accord with the hypothesis that the syndrome of cobalt deficiency in the ruminant is the result of a metabolic defect arising from a profound deficiency of vitamin B_{12}. Ruminants apparently require much more vitamin B_{12} than other animals, but the reason for this is not yet clear. There is no evidence that cobalt performs any physiological function in the tissues of animals other than as a constituent of vitamin B_{12}. The details of these experiments will be published elsewhere.

Influence of Cobalt on the Production of Factors possessing Vitamin B_{12}-like Activity in the Fæces of Sheep

WE have estimated the vitamin B_{12} and similar factors in the urine and fæces of a number of sheep which were confined in metabolism cages and fed on cobalt-deficient rations, and which were employed by Marston and Smith[1] for the experiments referred to in the preceding communication.

During the collection periods referred to here, an aliquot of the urine passed each day was treated with cyanide, adjusted to pH 6·8 and stored at − 20° C. until composite samples were made up immediately before the assays were conducted. Aliquots of the fæces were taken each day and stored at − 20° C. in sealed containers until required.

Table 1. Effects of Administration of Cobalt and of Vitamin B_{12} on the 24-hr. Excretion of Vitamin B_{12}-like Substances in the Urine and Fæces of Sheep on Cobalt-deficient Rations

Sheep No.	"Vitamin B_{12}" in urine (μgm.) (*L. leichmannii*)		"Vitamin B_{12}" in fæces (μgm.) (*E. coli*)		(*L. leichmannii*)		Treatment in period *B*

5012	0·52	0·26	2·0/1	3·8	0·74	5/1	Cobalt (*per os*)
9072	0·50	0·21	2·4/1	0·46	0·25	1·8/1	Vitamin B_{12} (parenteral)

The active material in the urine was measured by its capacity to promote the growth and lactic acid production of *Lactobacillus leichmannii* 313 under strictly controlled conditions. Extracts of the fæces were analysed by this method and also by the plate method of Harrison *et al.*[2], in which the test organism is a mutant of *Escherichia coli*. The results are shown in Tables 1 and 2. All animals had been on the deficient rations for 35 weeks before the treatments were begun. Period *A* was the 14 days immediately prior to treatment; period *B* was the 14 days beginning a fortnight after treatment was started. The first three animals were in an advanced stage of the cobalt-deficiency syndrome and their food intake in period *A* was less than 250 gm. per day; in period *B* animals No. 5009 (cobalt) and No. 7019 (vitamin B_{12}) consumed more than double this amount, whereas the intake of No. 7009 (untreated) remained practically unchanged. The second three animals had not become sufficiently depleted for their appetites to fail and consumed the whole of their rations, 1,050 gm. a day, in period *A*. The intakes of No. 5012 (cobalt) and No. 9072 (vitamin B_{12}) were unchanged in period *B*, but No. 9090 (untreated) began to lose its appetite[1].

Ford and Porter[3] have reported that several "B_{12}-like factors" occur in the fæces of calves, and that these differ in their capacity to promote the growth of the two micro-organisms *E. coli* and *L. leichmannii*. We have found that the estimate of vitamin B_{12} activity in sheep fæces obtained with *E. coli* as the test organism was always higher than that with *L. leichmannii*. The relation between the two measurements has been expressed as a ratio (Table 2).

In the fæces of the cobalt-deficient sheep, the ratio was between 1·4 and 2·4 to 1. After the animals had been treated with cobalt (1 mgm. per day *per os*), each method of assay showed an increased concentration of 'vitamin B_{12}', and the ratio rose to 5 or higher. Injection of vitamin B_{12} (50 μgm. a day) into the animals had no appreciable effect on the vitamin B_{12}-like activity of a given weight of fæces.

It would seem that there are at least two "B_{12}-like factors" in sheep fæces and that their absolute and relative concentrations depend upon the level of available cobalt in the gut.

Possibility of the Quaternary Fission of Uranium-235

IN their classic paper[1] discussing the theory of the fission process, Bohr and Wheeler estimated the energy release to be expected in binary, ternary and quaternary fission of the compound nucleus of uranium-239. In the binary case, for fragments of equal mass, an energy release of 200 MeV. was obtained; for three nearly equal fragments, the energy release is slightly greater, being about 210 MeV., while for division into four comparable parts it falls to 150 MeV.

Experimental observation of the quaternary fission of uranium-235 was claimed by Ho, Tsien, Vigneron and Chastel in 1946 [2], when they observed an event in a photographic emulsion which they believed could be represented best as four-particle fission into masses of 81, 99, 36 and 20. In the analysis applied, there are an infinite number of solutions for the mass values but the chosen one gave a kinetic energy release of 114 MeV., which they regarded as fitting the theoretical estimate well. A second case, reported in 1947 [3], had three heavy fragments and one light fragment, and the estimated masses were given as 84, 76, 72 and 4, and the total kinetic energy release as 102 MeV. These two events occurred in the examination of 10,000 binary fission tracks, and the frequency of quaternary fission was derived as 0·0002 ± 0·00015 of that binary fission.

In a recent detailed study of the slow neutron fission of uranium-235 with special reference to rare modes of fission[4], more than 600,000 binary fission events have been examined. Some 1,000 ternary events with a long-range light fragment have been observed in this work, but only two events were recorded which could possibly be classed as quaternary fission. The two events concerned are small, having a maximum particle range of 14 μ. This makes measurement difficult, particularly with a heavily ionizing track suffering from multiple scattering, and analysis of the type employed by Tsien *et al.* does not yield satisfying results. It is not possible to determine whether the events are truly quaternary fission or whether they are explicable as due (1) to recoils projected by the pair of fission fragments in the act of separating, or (2) a ternary event with a random track superimposed. In any event, if quaternary fission is a physical possibility, these experiments suggest that the cross-section given by the French group is too high by at least a factor of ten.

Quaternary fission has also been looked for in the fast neutron fission of uranium and thorium[5], and the photo-fission of uranium[6] and thorium[7]. No evidence for fission into four fragments of equal mass has been found in these experiments, although in the photo-fission of uranium[8] and the fast neutron fission of thorium[9] an event consisting of the two heavy fission tracks and a pair of α-particles has been observed. In each case it was possible to show[8,9] that the disintegration could be explained as a ternary fission in which the third nucleus was the unstable beryllium-8 emitted in the ground-state and which immediately broke up into a pair of α-particles.

This body of evidence suggests that quaternary fission is a highly improbable process whatever the nucleus and mode of excitation.

Viscosity and Thermal Conductivity of Liquid Argon

SOME time ago[1], I put forward certain very simple suggestions concerning the mechanism of the viscosity of liquids. These notions led to, among other things, a formula for the viscosity of simple (monatomic) liquids at the melting point which has been surprisingly successful in representing the melting point viscosity, η_M, of liquid metals[2]. My assumption is that in a simple (monatomic) liquid at melting point the atoms are vibrating about a mean position which very slowly migrates, and that momentum is transferred from layer to layer of the liquid at the extreme librations. This gives for the viscosity at melting point:

$$\eta_M = A\frac{\nu m}{\sigma}, \tag{1}$$

where ν is the frequency, m the mass of the atom and σ the interatomic distance, while A is a constant the precise calculation of which would be very difficult, but which must be about 1. I took it as 4/3 in my original paper.

Now if this simple theory has any physical meaning, the ratio of the thermal conductivity k to the coefficient of viscosity at the melting point should be given by considerations similar to those which apply in the case of gases. We are led to the formula:

$$\frac{k}{\eta} = Bc_v, \tag{2}$$

where c_v is the specific heat in cal. per gm. at constant volume and B is again a constant which should be about 1. This formula should apply to monatomic liquids but, among them, not to metals, since with these the heat is transferred mainly by electrons, which transport very little of the momentum.

The recent determination of the thermal conductivity of liquid argon[3] enables us to test (2). The thermal conductivity extrapolates to $3·08 \times 10^{-4}$ at the melting point, the viscosity[4] to $2·82 \times 10^{-3}$, which gives $k/\eta = 0·109$, while c_v at the melting point[5] is 0·138 cal./gm. The value of B therefore comes out to be 0·8, which is as near 1 as we can well expect with an approximate formula of this kind.

Theories of Magnetic Storms and Auroræ

RECENT theories of magnetic storms and auroræ due to Alfvén[1] and Martyn[2] have had considerable success in explaining various observations, though Alfvén and Chapman have both pointed out[3] that the most satisfactory test of these theories would be an experimental one. Further insight into these theories may also be expected using a different theoretical approach: instead of calculating typical orbits for the particles, the continuous gas model may be used. This facilitates the use of Maxwell's equations in considering the effect of the charged particles on the electromagnetic field; the knowledge gained about the field can then be used in discussing the orbits.

This approach leads to a criticism of that aspect of the theories mentioned which concerns the acceleration of the auroral particles; the acceleration of these particles gives rise to a 'back effect' which has not been taken into account by Alfvén or Martyn. In both theories the auroral particles are supposed to be accelerated by a steady electric field occurring within a few earth radii of the earth, although the mechanism by which this field is supposed to be set up is different in the two theories. If there were a region containing such an electric field, it is obvious that all charged particles in that region would be accelerated, and, if they were to acquire the necessary energy of 10 keV., all the electrons in this region would be moving in nearly the same direction with velocities of 6×10^9 cm./sec. Then if there are 100 electrons per c.c., as inferred from one theory, the current density is 300 e.s.u., which is relatively large, and Maxwell's equation:

$$c \operatorname{curl} \mathbf{H} - \partial \mathbf{E}/\partial t = 4\pi \mathbf{j},$$

must be considered. The displacement current becomes important only for phenomena at radio frequencies, so that $|\operatorname{curl} \mathbf{H}|$ must be of the order of 10^{-7} gauss/cm., which again is relatively large. Just how curl H attains this magnitude must be discussed using another of Maxwell's equations:

$$\partial \mathbf{H}/\partial t = - c \operatorname{curl} \mathbf{E}.$$

I have investigated this question[4], using the approximation $\mathbf{E} = - \mathbf{u} \wedge \mathbf{H}/c$, where $\mathbf{u}$ is the bulk velocity of the gas; this approximation is valid before the current density becomes large and is therefore good enough to decide whether the current density becomes large. The point of the discussion is that the magnetic field reacts on the gas through the force density $\mathbf{j} \wedge \mathbf{H}/c$, and, since the temporal rate of change of the magnetic field depends on the velocity of the gas, the important question is whether this force density favours or opposes the type of motion which will increase $|\operatorname{curl} \mathbf{H}|$ and therefore also increase the current density. It is found to oppose this type of motion except in the neighbourhood of a neutral point of the magnetic field, and hence, if $|\operatorname{curl} \mathbf{H}|$ is to be increased elsewhere, some force is needed 'to drive the dynamo'. Alfvén and Martyn have not allowed for this reaction of the field on the gas, and it is therefore doubtful whether the accelerating processes they have proposed can occur.

The suggestion that an electric discharge would occur at a neutral point was first made by Giovanelli[5] in connexion with solar flares, and Hoyle[6] has proposed a theory of the aurora in which the auroral particles are accelerated at neutral points. The neutral points are due to the combination of the magnetic field of the earth and a magnetic field carried out from the sun. Alfvén's model does, in fact, incorporate a magnetic field of solar origin, and further discussion of all aspects of such models seems likely to be fruitful.

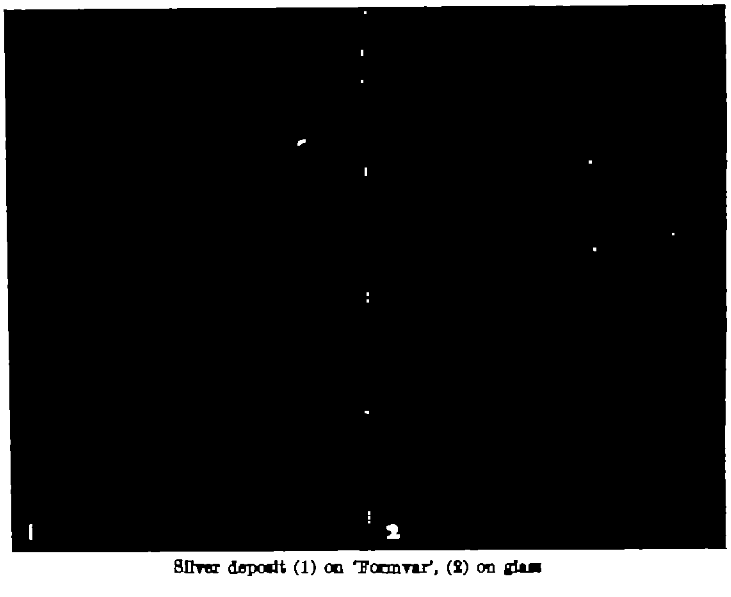
Thin Glass Layers as Supports for Electron Microscopy

IN the usual technique of electron microscopy, 'Formvar' or collodion layers are used as supports. We have been studying the electrical properties of thin metallic layers and determined their structure by means of the electron microscope. The electrical resistances were made on glass strips, while 'Formvar' layers were used as support for the electron microscope examination. We have always hesitated to consider the picture obtained on 'Formvar' as identical with the structure obtained on the glass surface; therefore we tried to use very thin glass layers as supports, and eventually succeeded.

The technique is as follows. A closed glass tube is heated in a coal gas – oxygen flame and blown out suddenly into the air. Thus the room is filled with very small pieces of glass flakes floating down to the floor. The thickest ones come down first, while the



Silver deposit (1) on 'Formvar', (2) on glass thinnest ones fall very slowly. The thin pieces of glass are caught on the surface of a vessel filled with water. Afterwards they are taken up from this water surface on the silver support for the electron microscope. The water is sufficient for the adhesion of the glass layer to the support. It is better, however, to fix the glass layer at one point by means of 'Formvar' used as adhesive material. In Figs. 1 and 2 are reproduced pictures, taken with a Philips electron microscope (*E.M.* 100), of the same silver layer obtained by sputtering on glass and the other on 'Formvar'. The magnification is about 20,000 for each.

It can be seen that the pictures obtained are similar in first approximation and are composed of small grains on a continuous underlayer. However, the grains on glass seem to be somewhat larger, as is also the separation between them. The macroscopic thickness, evaluated by weighing a test-plate, was found to be 950 A.

We are now trying to use much greater magnifications by making still thinner glass layers. At present the glass layers are made from Jena Gerate Glass 20.

We wish to thank the Centre Belge des Brasseries et des Malteries for financial help for this research.

Dielectric Constant of Water Films

In order to explain some recent high-frequency (430 Mc./s.) measurements by Cownie and Palmer[1] on the variation in the dielectric constant of moist clay with water content, it was assumed[2] that the dielectric constant of the water increased exponentially from 3 (the high-frequency value for ice) at the water – clay boundary to 80 (the normal value for water) at an infinite distance from the boundary. It was supposed that the maximum change occurred in the thin layers of water close to the solid, and that the effects extended into the bulk of the liquid for appreciable distances.

That thin layers of water do exhibit abnormal mechanical and electrical properties is well known, and the terms 'bound' water[3] or "l'eau "solide" "[4] have been used to indicate the ice-like properties of thin water films. The restricted movement of such 'bound' water molecules would presumably result in a value of the dielectric constant less than the normal value of 80.

In addition to the assumption that the dielectric constant of a water film varies with its thickness, it was found desirable to make a further assumption that the clay particles were both uniform in size and spherical in shape, although no steps had been taken to ensure this when the original experiments were undertaken. Consequently it has been decided to continue the investigation into the dielectric constant of thin water films by using certain composite or 'synthetic' dielectrics which are more amenable to theoretical treatment than is a clay – water mixture.

Preliminary experiments were made at frequencies of 2 and 3 Mc./s. with thin mica plates separated by layers of water. It was found that the dielectric constant of the water decreased with the thinness of the film from more than 20 for films about 5 μ in thickness to less than 10 for films about 2 μ in thickness (thickness calculated assuming no absorption). Even with very wet composite dielectrics, the dielectric constant of the water did not exceed 60.

It is known[5] that the dielectric constant of ice at a temperature not very much below 0° C. changes rapidly from about 90 to 3 when the frequency increases from just below to just above 10 kc./s. It was therefore thought that 'solid' water might exhibit a comparable variation about this frequency. To test this possibility, composite mica – water dielectrics were measured at 2 Mc./s. and at 2·5 kc./s. The value of the dielectric constant of the block of dielectric at the lower frequency was approximately double the value obtained at the higher frequency, indicating that the value of the dielectric constant of the inter-layer water was probably trebled or even quadrupled. In order to prevent evaporation between successive measurements, it was not possible (in these preliminary experiments) to make the necessary weighings which would enable the dielectric constant of the water alone to be calculated. A check experiment showed that the dielectric constant of the mica remained constant for this range of frequencies. Thus, since the dielectric constants of both water and mica are not frequency-sensitive over the range of frequencies used, whereas ice is frequency-sensitive at about 10 kc./s., it would appear that the water film is tending to act not as 'solid' water but rather as 'liquid' ice.

This is perhaps a subtle distinction; but it is an important one when problems relating to the dielectric properties of thin water films are under consideration. It is also conceivable that this point of view may contribute to a better understanding of the abnormal mechanical properties of thin liquid films.

Further experiments are in progress to confirm these conclusions, and it is proposed to extend the investigation to various forms of 'synthetic' dielectrics with liquids other than water as the matrix. We are indebted to our colleague Mr. J. Muir for assistance with the lower-frequency measurements.

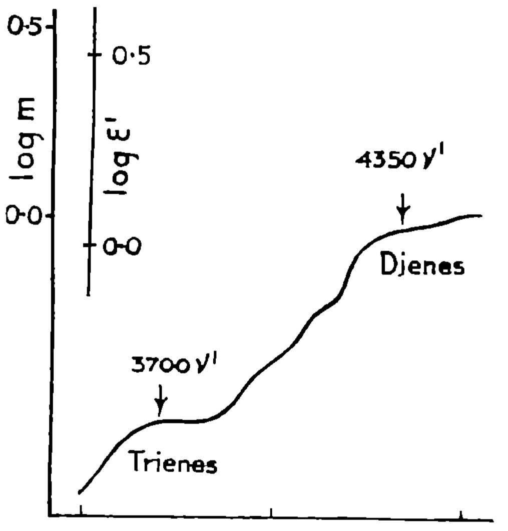
Relations between Small-Angle Interferences of Silk and the Wax Content

In previous papers[1] it has been established that alkali treatment of fresh preparations of silk fibroin gives rise to the appearance of new equatorial small-angle reflexions which were believed to be higher orders of a ground-period of 45 A. At first this effect was ascribed to a structural change of the silk lattice. Continued investigations, however, made it very likely that the new reflexions are due to some waxy substances. This assumption has now been confirmed by means of the following experiments : (1) The new reflexions disappear if the sample is treated with 1 : 1 ether–alcohol for 8 hr. at 40° C. (2) After removing the solvent by evaporation, a waxy substance (1·6 per cent of the weight of the degummed silk) is obtained. This is in good accordance with the data of other authors, who have found 1–2 per cent wax in *Bombyx mori* silk[2]. The extracted substance shows sharp reflexions corresponding with the net-plane distances given in column 2 of the accompanying table. Column 1 gives the net-plane distances of alkali-treated fresh silk samples, and shows the good accordance between the inner reflexions of the extract and the strongest ones of the alkali-treated silk. The outer reflexions of the extract identify the substance as probably a wax. It is to be noticed, however, that the reflexion corresponding to the smallest angles is not so sharp. (3) Extracting the alkali-treated silk with ether–alcohol gives also a waxy residue (1·6 per cent of the degummed silk) showing practically the same diagram as is described under (2). (4) The ether–alcohol solution shows absorption bands in the ultra-violet at 3,700 and 4,400 mm.$^{-1}$ which are characteristic for conjugated unsaturated fatty acids. The extracted fat (or wax) contained 0·8 per cent conjugated dienes and 0·2 per cent trienes.

Net-plane distances (A.)	Reflexions (A.)
45	45
16	15
9·3	9·8
4·20	4·06
3·46	3·70
3·01	3·25
2·50	2·68
2·25	2·40
	2·22

This was to be expected, since Bergmann[4] has found liquid fatty acids in extracted silk wax, and linoleic and linolenic acid have been extracted from cocoons of *Bombyx mori*[6]. Bergmann, investigating the relations between fat content and mechanical properties, could not find any quantitative relations and concluded that the wax simply protects the fibre against wetting influences'. (5) Films of 'renatured' silk after alkali treatment do not show any new reflexions, as stated in previous papers[3].

The appearance of the new small-angle reflexions in the X-ray diagram of alkali-treated fresh samples of silk indicates that the hot alkali brings the primarily amorphous waxy substances to crystallization. Apparently the fresh samples with well-formed intermicellar spaces give better chances for such crystallization than older preparations with probably closer-packed units.



The net plane corresponding to the large wax period runs parallel with the well-developed plane of the micelles (grid-plane). Since this period coincides apparently with the longitudinal extension of the wax molecules, it seems probable that the chains of the fatty acids stand more or less perpendicular to the grid-plane of the micelle. This points to some interaction with the polar side-chains of the fibroin.

The fact that the silk fat (or wax) is primarily not crystallized points to a very subtle and perhaps monomolecular distribution.

Since it has been stated that unsaturated fatty acids promote distinctly the polymerization of proteins in general, and since Müller[7], for example, has shown that the fibrous denaturation of globular serum proteins is rendered possible by lipoidal substances, one is tempted to suggest also a functional significance for the silk fat in the transformation of the globular into the fibrous form.

We are indebted to Mrs. O. Gold for experimental assistance.

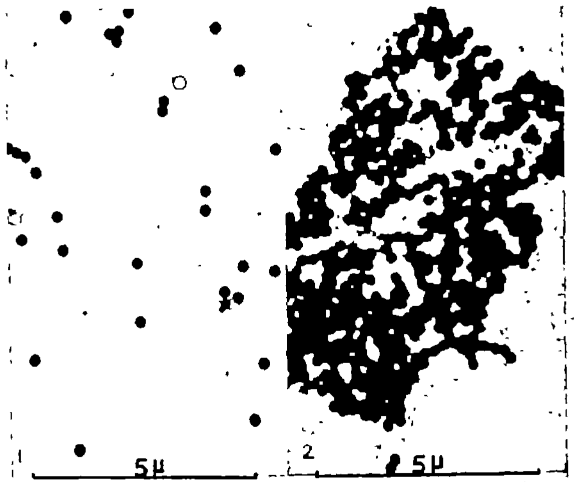
Resuspension of Dow Latex '580*G*' by Ultrasonics

Attempts to resuspend a sample of Dow polystyrene latex '580*G*'[1], which had dried out from 40 per cent suspension, by wet grinding and by shaking with water were only partially successful. Ultrasonic dispersion has been used and found to be successful under certain conditions.

Quantities of approximately 2·5 mgm. solidified latex in 10 ml. of soft tap water (hardness 20–30 p.p.m.), in a glass test-tube, diameter 2 cm., were placed in an oil-bath over the centre of a quartz crystal generating approximately 100 W. ultrasonic energy. Samples were treated for 30 sec., 90 sec., and 15 min., respectively, at 300 kc./s. with a continuous dissipation of approximately 10 W. in the sample. The suspensions produced were all found to be stable. Specimens prepared in an identical manner were examined in the electron microscope in an unshadowed condition, together with a sample of Dow latex '580*G*', which had not previously dried out, supplied by Dr. V. E. Cosslett.

The 30-sec. sample contained several undispersed fragments of the original solid together with single spheres and small planar groups. Very few fragments remained in the 90-sec. sample. The individual particles were still spherical and discrete (Fig. 1).



Ultrasonic treatment for (1) 90 sec., (2) 16 min.

The 16-min. sample, in addition to the usual single spheres and planar groups, contained many spheres which had been re-aggregated by the treatment and which had begun to coalesce, with a resultant loss of sphericity and diameter (Fig. 2). No such degenerate groups were found in the other samples.

As Jellinek and White[2] have shown that ultrasonic treatment of a polystyrene solution in benzene resulted in a progressive reduction of the average degree of polymerization, attention was paid to any possible changes in size and shape of the latex as a result of the treatment. Comparative measurements of the four samples were made at a fixed setting of the lens controls (magnification approximately 20,000) using several grids from each sample in order to minimize errors due to possible small magnification fluctuations between grids. No significant change was found in sphere diameter in either the 30- or 90-sec. treated samples, and it is concluded that a period of 90 sec. gives satisfactory resuspension. It is probable that the duration is not critical. It should be mentioned that in the samples from both sources a very small proportion of spheres appreciably larger or smaller than the average size exists, but these are quite readily recognized.

It is interesting to note that conditions for satisfactory resuspension of the latex are the same as those previously found by one of us (P. H.) for producing a stable carbon-black dispersion in water. The main requirements are: (*a*) low concentration of solid in liquid; (*b*) short period of ultrasonic treatment, usually less than 2 min. with the unit described above; (*c*) soft tap water. If these conditions are not satisfied, then a coarse dispersion is formed which settles out.

Chemical Mechanism of Permanent Set

Some years ago[1] it was argued that the permanent set which strained wool fibres acquire in steam is due to two consecutive intramolecular reactions, namely, disulphide bond breakdown, which leads to the dissipation of stress, and linkage rebuilding, which stabilizes the relaxed structure. Indirect evidence of many kinds led to the conclusion that the reactions take place according to the following scheme:

$$R.CH_2.S.S.CH_2.R + H_2O \rightarrow R.CH_2SH + R.CH_2.SOH$$
$$R.CH_2.SOH + H_2N.R' \rightarrow R.CH_2.S.NH.R' + H_2O.$$

Following a suggestion of Phillips[2], evidence was afterwards obtained[3] that, when alkalis are used as setting assistants, —CH=N— as well as sulphenamide linkages are formed:

$$R.CH_2.SOH \rightarrow R.CHO + H_2S$$
$$R.CHO + H_2N.R' \rightarrow R.CH{=}N{-}R' + H_2O.$$

The above conception of the chemical mechanism of permanent set has, however, failed to command general acceptance, because Cuthbertson and Phillips[4] and Lindley and Phillips[5] found little or no fall in free amino-nitrogen, as estimated by the van Slyke reagent, after wool had been boiled for 1 hr. with borate buffers at *p*H 8 or *p*H 10, nor was there any rise in the content of cysteine. Direct evidence that the lysine side-chains of wool take part in the linkage-rebuilding reaction has now been obtained in the following way.

Several bundles of Lincoln wool fibres were stretched 40 per cent and set by immersion in a boiling 2 per cent solution of borax for 1 hr. After being washed in several changes of distilled water, the wool was treated with 1-fluoro-2 : 4-dinitrobenzene for 48 hr. at 37° C. under Sanger's conditions[6]. The fibres were washed thoroughly with alcohol and water before being hydrolysed for 24 hr. with 6 *N* hydrochloric acid, and the ε-N-dinitrophenyllysine was estimated after separation on a silica column in the usual way. Four sets of experiments were carried out, and the lysine content of the set fibres, after correction for decomposition during hydrolysis, was found to range from 2·15 to 2·53 per cent. Since the lysine content of the untreated wool, determined by the copper-complex technique[7], was 3·27 per cent, it is clear that the lysine content of wool is reduced when stretched fibres are set in a boiling solution of borax.

In another experiment, several bundles of set fibres were mixed and divided into two parts. One part was treated with 1-fluoro-2 : 4-dinitrobenzene, and the lysine content was found to be 2·02 per cent. When, however, the second part was hydrolysed with 6 *N* hydrochloric acid, without previous treatment with 1-fluoro-2 : 4-dinitrobenzene, the lysine content, estimated by the copper-complex technique, was found to be 3·33 per cent, the same as that of untreated wool. It is clear, therefore, that the lysine side-chains take part in the formation of new cross-linkages which are broken, with liberation of lysine, when the set fibres are hydrolysed in boiling 6 *N* hydrochloric acid.

Either —S—NH— or —CH=N— linkages would fulfil these requirements for, in experiments with model compounds, it was found that the sulphenamides are decomposed into sulphenic chlorides and amines by boiling 6 *N* hydrochloric acid. When the sulphenamides were boiled with hydrochloric acid in presence of mercaptans, disulphides were obtained.

Any rise in the cysteine content of set fibres would not, therefore, be detected in the hydrolysate if set is due mainly to the formation of sulphenamide cross-linkages.

We are indebted to the International Wool Secretariat for grants in aid of this investigation.

A Method for Overcoming 'Unsoundness' in Magnesian Limes

Building failures arising from the use of limes with a high content of magnesia have frequently been observed. These failures—such as spalling and blistering of plaster coats, disintegration of mortar joints and expansion of brickwork—are, according to Wells and others[1,2], caused by the slow hydration of the magnesia in these 'unsound' limes, and may extend over periods up to several years. Complete hydration of these limes can be obtained by treatment with high-pressure steam; this treatment, however, which is extensively used by American lime manufacturers, is expensive both in equipment and operation, and a simpler one is desirable. Experimental work in this Division has been based on the principle underlying Sorel cement manufacture, in which inert basic salts of magnesia such as magnesium oxychloride or magnesium oxysulphate are formed by the reaction between magnesium oxide and magnesium chloride or magnesium sulphate.

For the initial stages of the work in the laboratory, artificial mixtures of calcium oxide and magnesium oxide, prepared from the precipitated carbonates in proportions found in natural limestones, were used. The salts calcium chloride, magnesium chloride, magnesium sulphate and ammonium chloride were added to the samples, either in the hydrating water or after the hydration of the lime to powder or putty. In all instances the unsoundness as determined by a modified Le Chatelier autoclave expansion test (National Building Studies Special Report No. 3, 1948) was so reduced by calcium chloride, magnesium chloride and ammonium chloride that the material could be classed as sound. Magnesium sulphate was found to be much less effective than the other salts. The best results were obtained with calcium chloride added to the mixing water after hydration.

The salt treatment, when repeated with dolomite and magnesian limes made from natural materials, produced a similar decrease in expansion. On a pilot-plant scale the treatment proved equally satisfactory.

The effect of the salts on the general properties of mortars and plasters made from treated material has been investigated. The consistency, bulk density, workability and hygroscopicity were found to be practically unchanged, and the amount of water-soluble salts was well within the permissible limits. Plaster panels applied to a wall in the ordinary way are at present under observation.

The theoretical background of the reactions taking place in the process is being studied.

Salting-out Chromatography of Amino-acids and Peptides in Filter Paper and other Media

Earlier investigations in this Institute[1] have shown that substances like dyestuffs and some proteins show a very marked increase of adsorption on to filter paper and other adsorbents in presence of salts in large concentrations. The adsorption may thus be increased from practically zero (in pure water) to considerable amounts, and the phenomenon may be utilized for chromatographic separations, using salt solutions of lower concentrations or even water for the elution. Similarly, Holman and Hagdahl[2] found that the adsorption of fatty acids on to carbon from solutions in ethanol was very markedly increased if the solubility was reduced by adding water to the solution.

In general, it is to be expected that the adsorption will increase as the solubility is reduced by changes in the medium which do not appreciably affect the adsorbing surface[3]. Recently, we have found that amino-acids and peptides show the same phenomenon both on charcoal and filter paper, and it is possible to obtain very satisfactory paper chromatograms based upon the salting-out principle by using, for example, strong phosphate buffer solutions as a medium. Figs. 1 and 2 show some paper chromatograms obtained in this way. (In absence of salts the adsorption is very small.) It is interesting to note that the order of the R_F values is to a certain extent reversed as compared with ordinary partition chromatography in butanol - water systems.

There seems to be a tendency for the salt to collect at the solvent front in the paper even if evaporation is prevented, and therefore the best results are obtained if the original spots are applied at a considerable distance behind the front. This enrichment of salts towards the advancing front points to a negative adsorption of the salts, that is, the water is more strongly bound by the cellulose than are the salts. This provides the necessary conditions for a salting-out effect, which may, of course, also be regarded as a kind of partition between a salt-rich and a salt-poor medium. There may also be some relations between this phenomenon and those described by Herbert and Pinsent[4] and Martin and Porter[5], where a second phase is created in ethanol - water or 'Cellosolve' - water systems by salting out, by which suitable conditions for chromatography of some proteins have been realized. The analogy to the effects of high salt concentrations in counter-current extraction according to Craig should also be noted[6].

Fig. 1. Ascending filter paper (Whatman No 1) chromatograms by the salting-out method. Salt medium. 1 *M* Na_2HPO_4 + 2 *M* NaH_2PO_4. The substances were applied as spots along the upper line after the paper had been soaked with salt solution to the lower line. (1) 0 005 ml 0·25 per cent *dl*-leucine; (2) 0·0025 ml. 0·5 per cent *dl*-valine; (3) 0·0025 ml. 0·5 per cent *dl*-alanine; (4) 0 0025 ml. 0 5 per cent glycine; (5) 0·0025 ml. 0·5 per cent *dl*-methionine; (6) 0·0025 ml. 0 5 per cent *dl*-phenylalanine; (7) 0·005 ml. 0·25 per cent *dl*-tryptophane; (8) 0·01 ml. 0·125 per cent (*dl*-tryptophane + *dl*-phenylalanine + *dl*-leucine + glycine)

Fig 2. Same as Fig 1, but with the following substances: (1) 0·005 ml. 0·5 per cent *dl*-leucyl-glycyl-glycine; (2) 0·005 ml. 0·5 per cent *d*-leucyl-glycine; (3) 0·005 ml. 0·5 per cent glycyl-*l*-leucine; (4) 0·005 ml. 0 5 per cent glycyl-glycine; (5) 0·01 ml. 0·25 per cent glycyl-*l*-tryptophane; (6) 0·005 ml. 0·5 per cent glycyl-*l*-tyrosine; (7) 0·01 ml. 0·25 per cent (glycyl-*l*-tryptophane + glycyl-*l*-tyrosine), (8) 0·01 ml. 0·25 per cent (glycyl-*l*-tryptophane + glycyl-*l*-tyrosine + glycyl-glycine)

The principle appears to have wide applicability in chromatography, even if the large amounts of salt involved will sometimes present difficulties. On the other hand, the procedure can probably be used with advantage in many cases where lack of solubility in one phase makes it difficult to apply the partition method.

Paper Chromatography of Phosphoric Esters

Bandurski and Axelrod[1] have recently published a paper describing modifications in Hanes and Isherwood's method[2] for the separation of phosphorylated sugars and adenosine phosphates by paper chromatography. Since these modifications are in certain respects similar to those being employed in this laboratory, this opportunity is being taken of indicating briefly the methods in use here.

Upward migration at 4° C. on acid-washed[3] paper is used in a similar manner to Bandurski and Axelrod, but the solvents used (Table 1) give higher R_F values and shorter running times than Hanes and Isherwood's mixtures, and tend to give smaller spots than Bandurski and Axelrod's mixtures. R_F values are difficult to reproduce accurately, but typical values are given in Table 2. For the detection of phosphate spots on the finished chromatogram, Hanes and Isherwood's reagent has been modified to allow the papers to be dipped instead of sprayed, by replacing part of the water with acetone[3]. *Molybdate reagent*: 1 gm. ammonium molybdate is dissolved in 8 ml. water and 3 ml. concentrated hydrochloric acid; 3 ml. perchloric acid (70 per cent) are added, and the mixture diluted to 100 ml. with A.R. acetone. Heating and treatment with hydrogen sulphide are as in the original method. Compounds absorbing ultra-violet light are detected by Markham and Smith's[4] photographic method, using a solution of chlorine in carbon tetrachloride instead of a chlorine gas filter. This modification allows a 1-cm. quartz cell to be used.

These methods are being applied to the quantitative separation of phosphorus-containing compounds in extracts from baker's yeast using bands instead of spots of concentrated extract applied to the starting line of the chromatogram with a very slow pipette[5]. By this method a commercial sample of adenosine triphosphate has been resolved into six constituents (adenosine triphosphate, adenosine diphosphate, adenylic acid, pyrophosphate, orthophosphate and a trace of an unknown ultra-violet-absorbing constituent), and analysed with good overall recoveries of total phosphorus and acid-labile phosphorus after cutting out the bands and eluting them with water by the capillary elution method of Dent[6]. The method is very suitable for the separation of traces of material from large amounts of interfering phosphates, and by its use glucose-1-phosphate equivalent to 6 μgm. of labile phosphorus was separated from about 300

Stepwise Degradation of the Peptides liberated in the Transformation of Ovalbumin to Plakalbumin

In the transformation of ovalbumin to plakalbumin by a proteinase from *Bacillus subtilis*, a small amount of material containing non-protein nitrogen is released, which has been separated into three fractions, designated[1] *A*, *B*, and *C*. Amino-acid analysis of these fractions suggests that *A* and *B* are peptides composed chiefly of glycine, valine, aspartic acid and alanine, in the ratios 1 : 1 : 1 : 3 and 1 : 1 : 1 : 1, respectively, while *C* appears to be alanylalanine. As pointed out before[1], it is reasonable to suppose that the three peptide fractions arise all from the same segment of the ovalbumin molecule, represented by *A*. Accordingly, *B* and *C* should be identical with parts of *A*. The present investigation furnishes some evidence for this scheme.

In an attempt to establish the structure of the three ovalbumin peptides, each fraction was subjected to a stepwise degradation process. This was accomplished by successive removal of the N-terminal amino-acids according to a procedure based largely on Edman's[2] phenyl isothiocyanate method and applicable for use with small quantities of higher peptides. 5–30 micromoles of peptide were allowed to react with phenyl isothiocyanate in 2 ml. of a water – dioxane mixture (aqueous ethanol and acetone also proved satisfactory) at *p*H 8·0 and 40° C. The course of the reaction, in which one hydrogen ion is liberated per ammonium group, was followed and recorded by means of a Jacobsen–Léonis autotitrator[3], as illustrated by the curves in Fig. 1. After completion of the reaction, the content of the reaction vessel was transferred to a graduated tube, and excess reagent and dioxane were removed by continuous extraction with cyclohexane. The aqueous phase, containing the phenylcarbamyl peptide, was evaporated to a volume of 1 ml., acidified with 5 *N* hydrochloric acid to *p*H 1, and left standing at 75° C. for 1½–15 hr., depending on the ease of cleavage of the carbamyl peptide, to yield the 3-phenyl-2-thiohydantoin derivative of the N-terminal amino-acid and the residual peptide or amino-acid. The yield of thiohydantoin, which was removed completely from the graduated tube by continuous extraction with ether, was checked by measurement of its ultra-violet absorption as described by the Fraenkel-Conrats[4]. Hydrolysis of the thiohydantoin by barium hydroxide[5] yielded the terminal amino-acid, which was identified by filter-paper chromatography. The residual peptide or amino-acid solution was returned to the reaction vessel, brought to *p*H 5·8 with 1 *N* sodium hydroxide and then to *p*H 8·0 with a measured volume of 0·1 *N* sodium hydroxide. The entire procedure was then repeated.

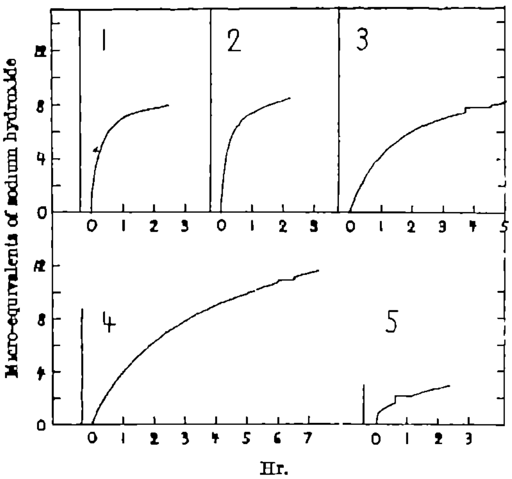

Fig. 1. Titration of terminal ammonium groups in the stepwise degradation of fraction *B*. Vertical lines in (4) and (5) titration from *p*H 5·8 to 8·0. Phenyl isothiocyanate added at zero time

By this method it could be confirmed that fraction *C* is alanylalanine, the first two degradation steps yielding equal quantities of alanine and the third step nothing. Similarly, fraction *B* could be identified as consisting, apart from an impurity containing glutamic acid (which may be a contamination from the bacterial enzyme preparation[6]), chiefly of alanylglycylvalylaspartic acid. This can be seen from the chromatogram reproduced in Fig. 2, in which the four component amino-acids appeared in the order indicated in the successive barium hydrolysates. The fifth run gave a blank, showing that one was dealing with a tetrapeptide. The titration curves in Fig. 1 indicate that during the entire degradation procedure there was little loss of peptide in the water phase, the amount of base consumed per ammonium group decreasing only slightly from one run to the next.

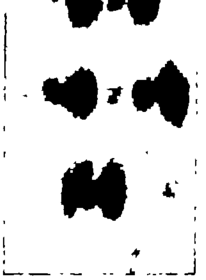

Fig. 2. Chromatogram of successively removed N-terminal amino-acids in fraction *B*. Whatman paper No. 1; phenol–water; descending chromatogram. Standards, from above to below: aspartic acid, glycine, alanine, valine. The spot in run 1 occupying a position between aspartic acid and glycine is due to glutamic acid

Stepwise degradation of fraction *A* yielded, beside unspecified amounts of glutamic acid[5], chiefly alanine as the first, and glycine as the second, amino-acid. In the third step valine and in the fourth step aspartic acid made their appearance. The chromatograms also showed spots due to glycine and valine, and particularly large spots due to alanine in the third and fourth steps. Analysis of the water phase following the second acid treatment revealed that alanylalanine had been liberated during this part of the procedure. By more drastic acid treatment most of, if not all, the remaining alanine could be split off as alanylalanine. Incubation of the original *A* fraction with carboxypeptidase resulted in the liberation of approximately one-third of the total alanine as free alanine. These observations indicate the presence of alanylalanine at the carboxyl end of fraction *A*, in all likelihood linked to the rest of the fraction through aspartic acid. In summary, analysis of fraction *A* to date indicates that it contains as a chief constituent the hexapeptide, alanylglycylvalylaspartylalanylalanine. It may also contain other peptides which may be products of the 'unspecific' breakdown of ovalbumin.

A detailed account of these experiments will appear in the *Comptes Rendus des Travaux du Laboratoire Carlsberg* (Série Chimique). We wish to express our gratitude to Prof. K. Linderstrøm-Lang for encouragement and suggestions throughout the course of this work.

Preparation of Crystals containing the Plakalbumin-forming Enzyme from *Bacillus subtilis*

OVALBUMIN is transformed by a proteolytic enzyme preparation from *Bacillus subtilis* into another protein, plakalbumin[1]. During the transformation a small amount of peptides is liberated[2]. An attempt has been made to purify the enzyme responsible for this transformation.

The bacteria were grown in submerged culture with vigorous aeration in a medium containing peptone, glucose and a salt solution containing trace metals. When after *c.* 30 hr. the enzyme concentration had reached a maximum, the bacteria were removed by centrifugation, the proteins in the culture liquid precipitated by addition of sodium sulphate, and the crude enzyme dried in a vacuum. A 10 per cent solution of the crude enzyme was purified by addition of calcium chloride in excess to precipitate the sulphate ions and of one volume of acetone to precipitate the mucins. The enzyme was precipitated by increasing the acetone concentration to 75 vol. per cent, and the precipitate dissolved in a small amount of water. After evaporation of the acetone, pH was adjusted to *c.* 5·5. The solution was made *c.* 5 per cent with respect to sodium sulphate, kept at *c.* 30° C. with mechanical stirring, and eventually seeded with crystals of the enzyme. When crystallization had started, the concentration of sodium sulphate was slowly raised to about 12 per cent. The enzyme crystallized out as long, very thin needles (see photograph). It was dissolved in water and recrystallized by addition of sodium sulphate. The activity of the enzyme was followed during the purification by measuring its ability to clot milk.

Plakalbumin-forming enzyme, recrystallized. × 300

	Per cent of original nitrogen	Per cent of original activity	Activity per mgm. nitrogen	Activity per mgm. protein nitrogen
Solution of crude enzyme	(100)	(100)	5,550	
Precipitate 50–75 vol. per cent acetone	72	95	7,300	7,550
Dissolved crystals after :				
1. crystallization	64	84	7,300	7,450
2. "	59	76	7,100	7,300
3. "	55	71	7,130	7,350
4. "	49	64	7,200	7,450

During the purification, the plakalbumin-forming ability of the enzyme follows the milk-clotting activity within experimental error. The enzyme breaks down casein at almost the same rate as trypsin and about three times as fast as chymotrypsin. It has no amylase activity. Preliminary investigations in the electrophoresis apparatus show that about 95 per cent of the material moves as a symmetrical peak in an acetate buffer with sodium chloride pH 5·3, ionic strength 0·1. In the ultracentrifuge the material appears homogeneous with a sedimentation constant of *c.* 2·7 Svedberg units.

We wish to express our thanks to Prof. K. Linderstrøm-Lang for his interest in this investigation, and to Dr. H. C. Hagedorn who instigated the work.

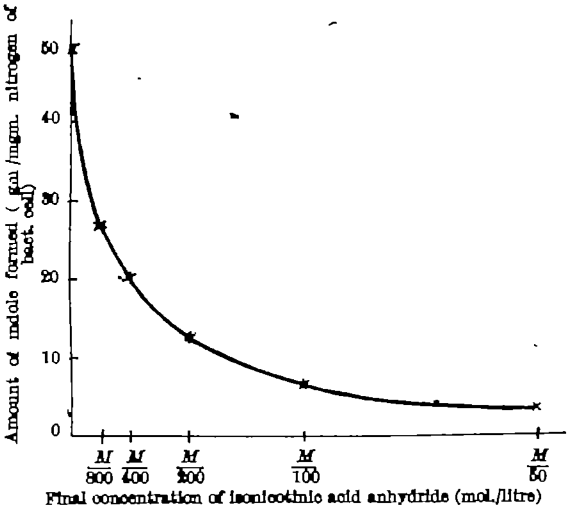
Competitive Action of Isonicotinic Acid Hydrazide and Vitamin B_6 in the Formation of Indole by *E. coli*

We have been seeking the mechanism to explain our observation that one of the substances which is contained in broth and is able to decrease the inhibitory effect of isonicotinic acid hydrazide on the growth of *E. coli* can, to some extent, be replaced by pyridoxine[1]. In further experiments, we have found that isonicotinic acid hydrazide considerably inhibits the formation by *E. coli* of indole, and that the activity of a suspension of *E. coli* treated with isonicotinic hydrazide recovers when the cells are in contact with pyridoxine.



Inhibitory activity of isonicotinic acid anhydride on the indole formation of *E. coli communior* (Exp. 1)

Typical results showing the inhibitory effect of isonicotinic acid hydrazide on the formation of indole by *E. coli communior* are given in the accompanying graph (Exp. 1), and the recovery effect due to pyridoxine is shown in Table 1 (Exp. 2). From the graph, it will be seen that the formation of indole by the washed suspension decreases considerably, generally in proportion to the amounts of isonicotinic acid hydrazide added; the rate of inhibition of isonicotinic acid hydrazide calculated from the results is given in Table 2.

The results in Tables 1 and 2 show that pyridoxine has a remarkable antagonistic action against the inhibitory effect on a cell suspension of isonicotinic acid hydrazide; for example, even 10^{-7} *M* (final concentration) of pyridoxine shows more than 50 per cent recovery effect.

In order to obtain the tryptophanase activity, the culture of *E. coli communior* (stock) was grown at 37° C. in broth containing 10 mgm./l. of DL-tryptophane for 18 hr. At the end of incubation, the organisms were centrifuged out of the growth medium, washed in saline three times and then made up into suspension in saline. The nitrogen content of the organisms per millimetre suspension was determined by the micro-Kjeldahl method as modified by Parnas.

Table 1 (Exp. 2). RECOVERY EFFECT OF PYRIDOXINE

Substrate. 0 4 ml. of *M*/160 DL-tryptophane in 3 4 ml. of reaction mixture. Reaction time. 10 minutes. Reaction temperature: 38° C.

0·02	92
0·01	86
0·005	74
0·0025	58
0·00125	45
0·0	—

As the preliminary experiments showed that contact for 30 min. was necessary for obtaining the complete action of isonicotinic acid hydrazide and of pyridoxine, suspensions of cells with the former or both of these substances respectively in phosphate buffer were incubated at 38° C. for 30 min. just before the determination of tryptophanase; the following quantities were used: in each test-tube, 0·5 ml. of washed suspension, 0·3 ml. of isonicotinic acid hydrazide solution, 1·9 ml. of *M*/15 phosphate buffer (*p*H 8·0), and in Experiment 2, 0·3 ml. of pyridoxine hydrochloride solution. The quantity of the liquid in each test-tube was made up to a volume of 3·0 ml. with distilled water.

In order to test the tryptophanase activity of these suspensions, the method of Wood *et al.*[2] with modifications was used throughout this work. The procedure is as follows: at the end of the contact, 0·4 ml. of *M*/160 DL-tryptophane was added to each test-tube and the reaction mixture was incubated at 38° C. for 10 min. The reaction was stopped by the addition of 0·2 ml. of 100 per cent trichloroacetic acid; and 2–5 ml. of toluene containing the indole extracted from the reaction mixture by shaking was mixed thoroughly with 5·0 ml. of Ehrlich's reagent (2 gm. paradimethyl-amido benzaldehyde, 40 ml. concentrated hydrochloric acid, 190 ml. of ethanol). After 10 min. reaction, 5·0 ml. of ethanol was added to dissolve the toluene and the red-coloured solution was used immediately for electrophotometric determination.

Since it is generally agreed that the coenzyme of the tryptophanase of *E. coli* is identical with pyridoxal phosphate[2], it is thus apparent from our results that isonicotinic acid hydrazide may act on the tryptophanase as an antimetabolite against the coenzyme, and that the considerable recovery effect of pyridoxine is due to the competitive action of the pyridoxal phosphate, which may be produced in the cell from pyridoxine added. These results point in the same direction as our experiments on the inhibitory action of isonicotinic acid hydrazide on the decarboxylation of amino-acids by *E. coli*[3]. Further research is now in progress. This work will be published in detail later.

Effect of D(+)-Leucine on the Hydrolysis of Glycil-L-Leucine in Normal and Neoplastic Tissues

In a previous paper[1], describing the beginning of a series of investigations on the action of D-amino-acids on L-peptidasic activity, it was observed that the effect of D(+)-leucine on hydrolysis of glycil-L-leucine by raw extracts of bovine intestinal mucosa clearly differed according to the *p*H of the reaction and to the final concentration of the D-amino-acid. D(+)-Leucine inhibited hydrolysis of glycil-L-leucine at a *p*H near the neutral point; it had no influence at an alkaline *p*H (8·5), while at an acid *p*H (6·2) it activated the reaction slightly.

Subsequent research showed that, when raw extracts of normal and pathological non-neoplastic human tissues were used in place of bovine mucosa extracts, the same results were obtained. The study of the effects produced by D(+)-leucine on the hydrolysis of glycil-L-leucine in human neoplastic tissues is therefore of considerable interest.

The material used in the present research consisted of twenty-five neoplasms (eight adenocarcinomas of the breast, three carcinomas (scirrhus) of the breast, one carcinoma of the gluteal zone, six carcinomas of the uterine cervix, two lymphosarcomas, two scapular sarcomas, two carcinomas of the rectum and one carcinoma of the penis). In all these cases it was definitely observed that D(+)-leucine affected hydrolysis of glycil-L-leucine in an entirely different way from that when normal and pathological but non-neoplastic human tissues were used; that is, from *p*H 6·2 to *p*H 8·5 it exerts a very marked activating influence. Such influence does not alter noticeably on varying the concentration of the D-amino-acid from 0·04 to 0·01 *M*; while at still lower molarity the activating effect decreases gradually, and ceases at a final concentration lower than 0·001 *M*. Control experiments with D(+)-leucine and extract alone were regularly made and no modifications at all were observed. When L(−)-leucine is used in place of its antipode, inhibitory action is, naturally, noted.

The method for the preparation of raw enzymatic extracts and for the tests of activity is described elsewhere[2], hydrolysis was determined by the measurement of liberated carboxyl groups[3], and in some experiments the liberated amino-groups were also determined (Van Slyke). For all tests, the temperature was 38° C., 0·1 *M* veronal buffer was employed and the *p*H controlled by means of a Cambridge *p*H meter, and the substrate solution was 0·025 *M* in the final reaction mixture.

Effect of D(+)-Leucine (L) on Hydrolysis of Glycil-L-Leucine (GL) by Human Non-neoplastic and Neoplastic Tissues

Conc. of D(+)-leucine	Time (min.)	*K* GL	*K* GL+L	Hydrolysis (per cent) GL	Hydrolysis (per cent) GL+L	Tissue
0·04 *M*	15	0·00305	0·00832	10	25	breast cancer
	30	0·00287	0·00780	18	42	
	60	0·00290	0·00824	33	68	
0·04 *M*	10	0·00315	0·00280	7	5	normal skin
	30	0·00305	0·00201	19	13	
	60	0·00319	0·00227	35	25	
0·01 *M*	10	0·00155	0·00700	3·5	15	uterine cancer
	30	0·00152	0·00602	10	34	
	60	0·00156	0·00562	19	54	
0·01 *M*	10	0·0173	0·0173	33	33	uterus, chronic metritis
	20	0·0173	0·0173	59	59	
	40	0·0159	0·0159	77	77	
0·01 *M*	5	0·0181	0·0309	14	39	adeno-carcinoma
	15	0·0147	0·0303	39	65	
	30	0·0136	0·0294	61	85	

Some of the results are shown in the table, where the values for hydrolysis are expressed as the first-order velocity constant calculated as a decimal logarithm (*K*); the *p*H is 7·2, since at this value D(+)-leucine (final concentration, 0·04 *M*) has a distinct inhibitory influence when non-neoplastic tissues are used.

Hence it is clear that the activating influence of D(+)-leucine on the hydrolysis of glycil-L-leucine (at *p*H 7·2) in the case of neoplastic tissues is just the opposite to the inhibitory one observed in normal and pathological non-neoplastic tissues.

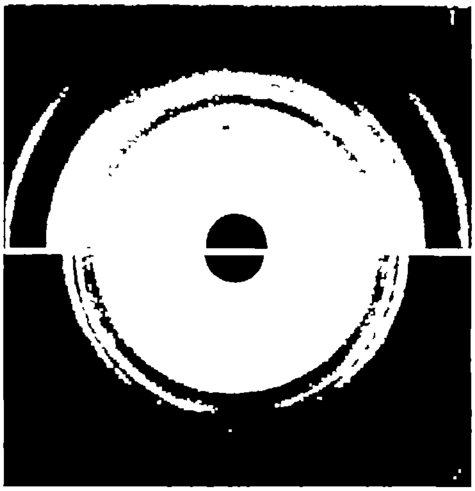
Isolation of Phosphothreonine from Bovine Casein

Lipmann has shown[1] that the phosphorus in casein is bound to serine, and this has been further confirmed by the isolation of crystalline phosphoserine in this Institute[2]; but it is also conceivable that a part of the phosphorus may be bound to threonine.

To investigate this, bovine casein was hydrolysed and a barium complex prepared, according to Lipmann. The barium was removed with a cation-exchanger ('Dowex 50'), and further purification was obtained by displacement on an anion-exchanger ('Dowex 2'), by the method of Partridge and Brimley[3]. For the final separation elution with 0·01 *N* hydrochloric acid from a 'Dowex 50' column was used. One of the fractions consisted, after evaporation, of lustrous stout prisms that yielded threonine after hydrolysis.

These prisms were compared with DL-phosphothreonine, synthesized according to Plimmer[4]. They had the same R_F value in paper chromatograms run with different solvents and the same melting point, 194° (decomp.). The crystals from the hydrolysate showed an optical rotation $[\alpha]_D^{24}$ − 7·37°, whereas the synthetic compound was inactive.



X-ray powder diffraction diagrams from (1) DL-phosphothreonine and (2) L-phosphothreonine

The X-ray powder diffraction patterns were identical. The molecular weight was 201·0 as calculated from X-ray diffraction data.

Analysis $C_4H_{10}O_6NP$ (199·1)				
Calculated	C 24·1	H 5·06	N 7·04	P 15·6
DL-Phosphothreonine	24·0	5·13	6·89	13·4
L-Phosphothreonine	24·9	5·19	7·03	14·0

The phosphorus was determined by Teorell's method[5]. The low figures seem to be due to difficulties in hydrolysing.

These facts seem to indicate that the phosphoric acid in casein is bound not only to serine, but also to threonine.

A full account of this work, which was sponsored by the Swedish Medical Research Council, will appear elsewhere.

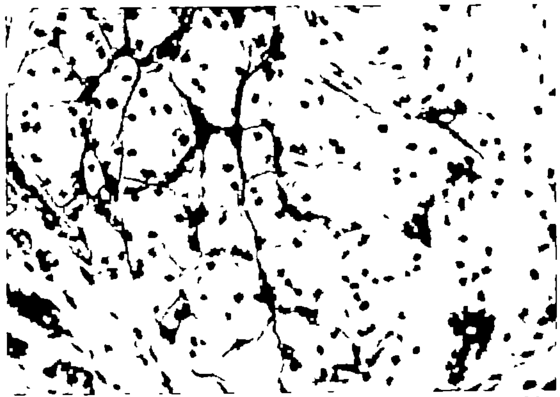
Survival of Adrenal Gland Homografts in the Rabbit's Skin

AN exception to the rule that tissue homografts in non-inbred mammals survive only for a few weeks has been observed in adrenal gland grafts transplanted from one adult rabbit to the skin of another. Such grafts live for many months, and appear to succumb finally to a type of disuse atrophy rather than to the usual homograft reaction.

Slices of adrenal gland including capsule, cortex and medulla, and weighing on the average about 25 mgm., were inserted into the fascial layer of the skin of the abdomen. At monthly intervals the grafts were exposed and measured and, beginning with the second month, tiny biopsy samples were taken. The grafts gradually diminish in size from the first month onwards.

Removal of one or both of the host's adrenal glands within five weeks of grafting was not followed by any noteworthy prolongation of the life of the graft or change in its histology. The chief determinant of the length of life of the graft appears to be the size of the original transplant; the results indicate that, in general, the bigger this is the longer will the graft survive. The biggest are still alive after seven months.

The medullary tissue did not survive, the grafts being composed of a capsule surrounding a mass of polyhedral cells which resembled enlarged zona fasciculata cells (see photograph). These cells gave positive reactions to tests for lipids, phospholipines, cholesterol and vitamin C, and there was a well-developed network of reticular fibres among them. They exhibited mitotic figures in a graft removed at two weeks, and in another removed at six weeks, after transplantation, but not in older grafts. Some of the signs of a homograft reaction, namely, infiltration of lymphocytes and plasma cells, and dilatation and congestion or destruction of the blood vessels, were observed in a few specimens, but they were usually weak or localized. The majority of grafts showed none of these signs.



Cells of an adrenal gland homograft after five months in the skin of a bilaterally adrenalectomized rabbit

The cells in most grafts undergo a slow process of degeneration. Their cytoplasm enlarges and frequently develops large fat droplets; the cell boundaries become indistinct and cells coalesce, so that multinucleate forms are common. Pyknotic and elongated nuclei are numerous in older grafts.

This degeneration of the homograft tissue is not surprising in normal or unilaterally adrenalectomized animals. But it also occurs in bilaterally adrenalectomized animals, and since these showed no distress after the disappearance of their grafts this suggests that accessory cortical tissue may take over the function of the glands. No cortical tissue was found on macroscopic examination of the sites of adrenalectomy at autopsy. The effect of later adrenalectomy and of implantation into the deeper parts of the body is now being tested.

The chief interest of the phenomenon lies in the apparent failure of the usual homograft reaction in these grafts and the indication that, contrary to the rule with other tissues, the larger the graft dosage the longer the survival. Submaxillary gland homografts transplanted to the same site and in the same dosage were found, when examined after two months, to be completely destroyed.

These findings are also of interest in relation to the reports of successful treatment of Addison's disease by means of adrenal gland homografts[1,2]. Lux, Higgins and Mann[3] reported survival up to twelve weeks of homografts of adrenal gland from new-born rabbits and guinea pigs when the grafts were first cultured in the presence of the host's serum and then transplanted into the groin. These grafts underwent a delayed, but ultimately strong, homograft reaction.

Oxidation of Thiophosphate Insecticides in the Rat

THE problems encountered in assessing the toxicity of the organo-phosphorus insecticides towards mammals have been reviewed in a recent article by Aldridge and Barnes[1]. It was pointed out that compounds such as O-*p*-nitrophenyl O,O-diethyl thiophosphate (parathion, *E* 605) are considerably more potent *in vivo* as inhibitors of true cholinesterase than would be expected from their inhibitory activity *in vitro*; the summarized evidence indicated that thiophosphates of this type are transformed into another more active inhibitor *in vivo*. It has been shown that the inhibitory action of technical parathion on true cholinesterase *in vitro* is due mainly, if not entirely, to an impurity of the form O-*p*-nitrophenyl O,S-diethyl thiophosphate[2]. Thus it was conceivable that the increased potency of parathion *in vivo* could be due to the formation of this S-ethyl isomer, but recent evidence seems to suggest that isomerization may not be the complete answer to this problem[3]. In the course of investigations on the selective inhibition of ali-esterase (tributyrinase), we have obtained evidence indicating that the thiophosphate insecticides may be oxidized *in vivo* to their phosphate analogues.

This conclusion is based upon a comparison of the relative inhibitory potencies of various analogous organo-phosphorus compounds towards the true cholinesterase and ali-esterase of rat brain *in vitro* and *in vivo*. Paraoxon (III) inhibits the true cholinesterase of rat brain more readily than the ali-esterase, both *in vitro* and *in vivo*, whereas the S-ethyl isomer of parathion (II) inhibits both enzymes to about the same extent *in vitro* and *in vivo*. A preparation of parathion (I) with a chemical purity of about 99 per cent also inhibited both enzymes equally well *in vitro*; but its inhibitory potency was only 1 per cent of that of the isomer (see table). These findings provide additional evidence in favour of the hypothesis that the inhibitory activity of parathion *in vitro* is due to the presence of a small amount of the S-ethyl isomer as impurity[2]. However, when this parathion preparation was injected into adult male rats, the true cholinesterase of the brain was found to be considerably more inhibited than the ali-esterase, as is also the case when paraoxon is injected. We surmise from these results that the inhibitory activity of parathion *in vivo* must be due largely to paraoxon, formed by enzymic oxidation of —P=S to —P=O.

There was some doubt as to whether this conclusion was completely justifiable because of the fact that the inhibitory action of parathion on the cholinesterase of rat brain is of fairly short duration[4], whereas that of paraoxon seems to recede less rapidly. However, the above hypothesis is strongly supported by the results obtained in experiments with the compound *bis*-(O-*p*-nitrophenyl) O-methyl thiophosphate (IV)[5], its S-methyl isomer (V) and the analogous phosphate (VI)[5].

True cholinesterase and ali-esterase activities of rat brain homogenate were determined manometrically with 0·03 *M* acetyl-β-methylcholine and 0·2 per cent tributyrin suspension as respective substrates[1]. The esterase inhibition *in vitro* was measured after incubation of the rat brain homogenate with the inhibitor in a 0·025 *M* bicarbonate buffer for 30 min. before the substrate was added. All inhibitor preparations had a chemical purity of 95–100 per cent[5] with the exception of the S-ethyl compound (II), which was 70 per cent pure; the concentrations of inhibitor are necessarily expressed in the table as molar concentration of crude preparation. The esterase inhibition *in vivo* was determined in the brains of adult male rats after intraperitoneal injection of the inhibitor solution; * indicates the appearance of muscular fibrillation and other symptoms of true cholinesterase inhibition[6,7]; † indicates one or two fatalities in a group of five rats before the time when the surviving rats were sacrificed. Compound V was obtained by isomerization of IV for 36 hr. at 140° C.; melting point after recrystallization, 106°–107° C.

In vitro, the phosphate ester is a selective inhibitor of true cholinesterase, while both the O-methyl thiophosphate and its S-methyl isomer are selective inhibitors of ali-esterase (see table). Whereas the O-methyl thiophosphate exhibits only 1 per cent of the inhibitory potency of the S-methyl isomer *in vitro*, it is significantly more active than this isomer against the true cholinesterase *in vivo*. Moreover, both the O-methyl thiophosphate and the phosphate ester are selective inhibitors of true cholinesterase *in vivo*, and only the S-methyl isomer inhibits the ali-esterase more strongly than the cholinesterase (see table).

Finally, it was observed that the initial esterase inhibition caused by the S-methyl isomer had almost completely disappeared 24 hr. after the injection of this compound into the rats; the inhibitory and toxic actions of the analogous phosphate, in contrast, continue to increase slowly between 4 and 24 hr. after injection. The effects of *bis*-(O-*p*-nitrophenyl) O-methyl thiophosphate *in vivo* are qualitatively identical with those of the phosphate analogue, and do not resemble those of the S-methyl isomer (see table).

Apparently the inhibitory activity of the O-methyl thiophosphate derivative *in vitro* is due to a contaminating trace of the S-methyl isomer; but its inhibitory action in the rat is probably due

COMPARISON OF THE INHIBITORY ACTIONS OF ORGANO-PHOSPHORUS DERIVATIVES ON THE CHOLINESTERASE AND ALI-ESTERASE OF RAT BRAIN *in vitro* AND *in vivo*

Compound	Molar concentration producing 50 per cent inhibition *in vitro* of		Amount injected (mgm / 100 gm.)	Per cent inhibition of esterases *in vivo*			
	True cholinesterase	Ali-esterase		1 hr. later: True cholinesterase	1 hr. later: Ali-esterase		
(I) O-*p*-Nitrophenyl O,O-diethyl thiophosphate (parathion, *E* 605)	$2·5 \times 10^{-6}$	3×10^{-6}	0·6	86*	36		
(II) O-*p*-Nitrophenyl O,S-diethyl thiophosphate	$3·6 \times 10^{-7}$	4×10^{-7}	2·0	69	62		
(III) *p*-Nitrophenyl diethyl phosphate (paraoxon, *E* 600)	$0·1 \times 10^{-7}$	2×10^{-7}	0·15	78*	26		
				4 hr. later: True cholinesterase	4 hr. later: Ali-esterase	24 hr. later: True cholinesterase	24 hr. later: Ali-esterase
(IV) *Bis*-(O-*p*-Nitrophenyl) O-methyl thiophosphate	$c.\ 10 \times 10^{-4}$	$0·6 \times 10^{-4}$	10	72	56	92*†	75
(V) *Bis*-(O-*p*-Nitrophenyl) S-methyl thiophosphate	12×10^{-6}	$0·8 \times 10^{-6}$	20	40	78	16	30
(VI) *Bis*-(*p*-Nitrophenyl) methyl phosphate	$0·3 \times 10^{-7}$	3×10^{-7}	2	80*	62	93*†	79

almost exclusively to the formation of the phosphate analogue. The quantitative difference, that is, the reduced toxicity of the O-methyl thiophosphate as compared with the phosphate analogue, could be explained by the various factors involved in the absorption and destruction of the injected thiophosphate before it is transformed into this phosphate. On the other hand, the S-methyl isomer does not appear to undergo any isomerization or oxidation *in vivo* and thus has essentially the same action *in vivo* as *in vitro*.

Should the effects described above be reproducible in other species, it would appear that the well-known differences in relative toxicity of analogous phosphates and thiophosphates towards various forms of life must be due mainly to differences in the water and lipid solubility of these compounds[8], and secondarily to differences in the ability of various animal species to oxidize and destroy the thiophosphates. The toxicity of the organo-phosphorus insecticides towards mammals seems to be dependent only on the inhibition of true cholinesterase[1,4,7]. Some of these compounds may also cause an appreciable inhibition of the ali-esterase in brain; however, no toxic symptoms are observed when the ali-esterase is inhibited selectively by *bis*-(O-*p*-nitrophenyl) S-methyl thiophosphate.

A detailed report of the investigations on ali-esterase inhibition will be published elsewhere.

Response to Vitamin B_{12} of Grazing Cobalt-deficient Lambs*

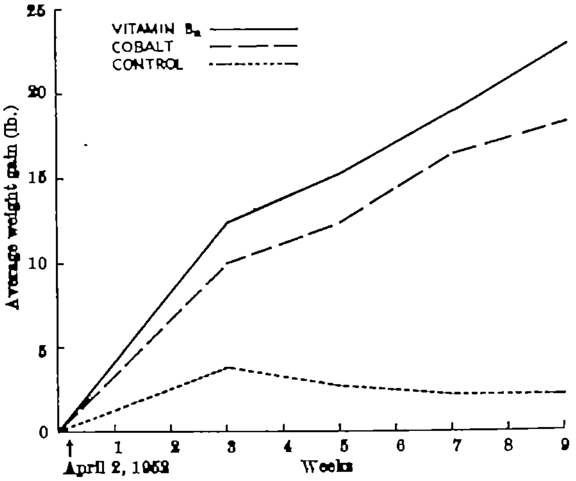
Smith and collaborators[1,2] have shown that vitamin B_{12} injected in sufficient quantity will alleviate the symptoms of cobalt deficiency in penned lambs fed a special low-cobalt ration.

Since cobalt deficiency in grazing lambs is not uncommon in New Zealand, it seemed desirable to test the curative action of vitamin B_{12} on unthrifty lambs grazing a pasture of low cobalt content. For this purpose suitable experimental conditions were available at the Winton Experimental Farm, Southland. Previous work[3] had shown that liver and pasture samples were low in cobalt content and unthrifty lambs had responded significantly to cobalt dosing.

In the present trial, Romney–Southdown crossbred lambs approximately 6½ months old were used. They had been confined to the same paddock since birth, and prior to the start of the experiment virtually all were showing signs of cobalt deficiency, as judged by small and erratic gains or actual losses in weight. Lambs were divided into three treatment groups as follows: (1) vitamin B_{12}-injected (4 lambs): 100 μgm. intramuscularly a lamb a week; (2) cobalt-dosed (19 lambs): 4 mgm. a lamb a week; (3) control (9 lambs).

Treatments commenced on April 2, 1952. All lambs were weighed at the start of the experiment, again three weeks later, and thereafter at fortnightly intervals until June 4. At the end of the nine-week experimental period, vitamin B_{12}-treated lambs had each received a total of 800 μgm. vitamin B_{12} and cobalt-dosed lambs each 32 mgm. cobalt.

Average gains in weight are set out in the accompanying graph. Responses to both vitamin B_{12} and cobalt are highly significant ($P < 0 \cdot 01$). Our figures suggest a more rapid response to vitamin B_{12} than to cobalt, but differences between the two groups do not attain significance.



These results show that, under the conditions of our experiment, grazing cobalt-deficient lambs respond at least equally as well to vitamin B_{12} as to cobalt. Australian workers[4] report a similar finding with adult merino ewes on low-cobalt pastures.

Induction of a Spawning Reflex in Hypophysectomized Killifish

The observations reported below were made during the course of a preliminary series of experiments with purified fractions of pollack pituitary glands, a study which I am undertaking in collaboration with Dr. A. E. Wilhelmi, Department of Biochemistry, Emory University, with the support of a grant from the U.S. National Science Foundation.

The test fish were two-year-old male *Fundulus heteroclitus* (L.), hypophysectomized at least two months prior to the experiment to allow time for the testes to undergo complete regression. Intraperitoneal injections of 1 per cent saline suspensions were made at a standard dosage level of 100 μgm./gm. weight. Controls, which exhibited no response, received an equivalent volume of saline. Details of the effective fractions are reserved for later publication.

All fractions so far tested contain the melanophore-contracting hormone and pallor begins to develop 5–10 min. after injection. Shortly thereafter with certain fractions, on the average in 17 min., the fish become excited and begin to exhibit violent S-shaped spasms. Each spasm lasts from a few seconds to a minute or more. The fins are in rapid vibration or, more rarely, the fish becomes temporarily 'frozen' in a state of extreme flexure. A peak of activity is reached in about 30 min., after which there is a slow decline: but in the most potent fractions occasional spasms may be observed for as long as 1½–2 hr. The direction of flexure is either to the right or left with approximately equal frequency. The fish show no interest in each other but behave independently. Although the response is, in this respect, abnormal, there can be no doubt that the spasms are typical of the spawning behaviour of this species as described by Newman[1].

One completely hypophysectomized fish was injected thrice weekly for four weeks. At autopsy, nuptial colours were lacking and the testes were in total regression. Evidently the hormone responsible for the spawning reflex is not associated with stimulation of the regressed gonads. Nor can the spawning reflex be elicited by injections of methyl testosterone into hypophysectomized males.

Further experiments were made with pairs of unoperated fish, mostly well in advance of normal spawning. The response is exactly the same as in hypophysectomized fish and was elicited equally well in either sex. With the exception of one pair which were close to normal spawning, the development of spasms was not accompanied by emission of eggs or sperm, even after a second or third injection. Young fish, taken in their first spring, were as responsive as those with previous spawning experience.

In an attempt to identify the fraction responsible for the reflex, both normal and hypophysectomized fish were injected with a highly purified prolactin preparation. No response was elicited. Normal fish of both sexes were also injected with purified mammalian follicle-stimulating and luteinizing hormone (Armour and Co.). The follicle-stimulating hormone was inactive; but five out of six fish receiving the luteinizing hormone responded with characteristic spasms. The response appeared more slowly than with fish pituitary preparations, in 42–63 min., and it was less frequent. The luteinizing hormone was tested on a completely hypophysectomized fish and the response developed belatedly, in 77 min.

It is well known that injections of fish pituitary induce spawning in fish well in advance of the breeding season. Gerbilsky[2], an advocate of the neurocrine theory of the spawning hormone, has used intracranial injections for more rapid and effective results; in *Acipenser* the injected fish behaved in a tempestuous manner, leaping out of the water and often injuring themselves. Noble and his associates[3] induced brooding behaviour in the jewel fish, *Hemichromis*, with various pituitary preparations and also with injections of phenol; previous spawning experience was shown to be necessary, but the response could then be elicited even after castration, and it was further demonstrated that the nervous centres associated with the response were located in the corpus striatum. The findings reported in the present communication appear to confirm the theory that the spawning hormone of fish may stimulate sexual behaviour by a direct action on the nervous system. Furthermore, this hormone is apparently related to mammalian luteinizing hormone, which induces a similar response.

The 'Double Bang' of Supersonic Aircraft

Two explosive sounds in succession have sometimes been heard when aircraft in the vicinity exceeded the speed of sound. As I am not aware of any discussion of this phenomenon, I wish to direct attention to its explanation.

The condition for a shock to reach the stationary observer (in stationary air) can be stated simply with the aid of Huygens's wavelets: it occurs when the wavelets emanating from successive elements of the path of the source (the aircraft) superpose at the observer. This will happen when $-\mathrm{d}r/\mathrm{d}t = c$, where r is the (scalar) distance between aircraft and observer, and c is the speed of sound. Whatever the speed of the aircraft, no bang is heard by an observer with respect to whom $-\mathrm{d}r/\mathrm{d}t$ never exceeds the speed of sound. If it does exceed it, then there must be the point on the track where $-\mathrm{d}r/\mathrm{d}t$ first became equal to c; and, as a high speed of approach cannot be maintained indefinitely (at most until $r = 0$), there must be another point where $-\mathrm{d}r/\mathrm{d}t$ becomes again equal to c. Each of these two points is the origin of a bang for the particular observer, who would measure the direction and time accordingly.

The bang which is heard first is the one which was generated second, and it is expected to be usually the louder, having the closer origin. The second one to be heard may have its origin far away and hence be faint; but only if the aircraft has been flying nearly directly towards the observer for a long distance, or has been exceeding the speed of sound by a large margin. The most likely case at present appears to be a pair of similar bangs in quick succession.

The part of space in which the bangs can be heard is defined by a surface opening out in the forward direction from the point on the track where the aircraft first reached the speed of sound. An observer on this very surface would hear the two bangs merged into one.

The engine noise arrives at the observer in a complicated way: *before* the first and *after* the second bang, the noise is heard singly and in the time sequence of its generation; between the two bangs, there are three components of noise, one of which is reversed in time.

Note added on October 16. My attention has now been directed to a popular article in *Flight* of October 3 on this subject. That article contains no mention of the essential significance of the 'velocity of approach towards the observer' as distinct from the airspeed, and hence does not contain the main argument presented here.

T. GOLD

Trinity College,
Cambridge. Oct. 5.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 10

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. C. A. Cotton: "Tectonic Relief".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. Henry E. Sigerist: "Landmarks in the History of Hygiene" (Heath Clark Lectures).* (Further Lectures on November 11, 12, 13 and 14.)

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. O. Wisdom: "A Theory of Psychosomatic Disorder".

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "The Teaching of Illumination Engineering".

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Dr. K. R. Capper: "The Extra Pharmacopoeia".

Chemical Society, Oxford Section (in the Physical Chemistry Laboratory, South Parks Road, Oxford), at 8.15 p.m.—Prof. G. E. Blackman: "Herbicides and Insecticides" (Alembic Club Lecture.) (All Fellows are invited.)

Tuesday, November 11

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. G. E. Blackman: "Factors Affecting the Selective Toxicity of Herbicides". (Further Lecture on November 18.)

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. C. A. Cotton: "Coastal Morphology and Classification".* (Further Lecture on November 13.)

Illuminating Engineering Society (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2) at 6 p.m.—Papers on "Factory Lighting".

Wednesday, November 12

Royal Sanitary Institute (at 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. H. E. Bywater: "The Hygienic and Economic Utilization of Offal and By-Products of Food Animals" (Benjamin Ward Richardson Lecture).

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. E. G. Richardson: "The Science of Musical Instruments".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. S. F. Birch: "Sulphur Compounds in Petroleum".*

Royal Aeronautical Society (at Vickers-Armstrong, Ltd., Weybridge), at 6 p.m.—Sir A. H. Roy Fedden: "Rex Pierson—an Appreciation and the Lessons of his Work" (First R. K. Pierson Memorial Lecture).

Royal Statistical Society, Study Section (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Discussion on "The Census 1951—1% Results" (Speakers: Mr. Harry Henry, Mr. E. Grebenik, Dr. J. Baxter).

Society of Cosmetic Chemists of Great Britain (at the British Colour Council, 13 Portman Square, London, W.1)—Dr. Stoves: "Hair".

Thursday, November 13

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. B. C. Brookes: "Words and their Definitions".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. R. H. Corkan and Dr. A. T. Doodson, F.R.S.: "Free Tidal Oscillations in a Rotating Square Sea"; Mr. J. Darbyshire: "The Generation of Waves by Wind".

Royal Institute of Chemistry, London and South-Eastern Counties Section (joint meeting with the University Chemical Society, in the Zoology Lecture Theatre, The University, Reading), at 8.15 p.m.—Dr. J. G. A. Griffiths: "Rockets and Chemistry".

Friday, November 14

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Prof. N. F. Mott, F.R.S.: "The Mechanism of Work-hardening in Metals" (Thomas Hawksley Lecture).

Institute of Physics, Industrial Spectroscopy Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Annual General Meeting; at 5.45 p.m.—Papers on "Vacuum Ultraviolet Spectroscopy".

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Dr. J. Carmichael: "Fine Chemicals in Veterinary Medicine".

Saturday, November 15

Biochemical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 10.30 a.m.—Symposium on "Immunochemistry".

British Psychological Society (in the Eugenics Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Prof. Sigmund Koch: "The Proper Functions of Theoretical Psychology".

Engineers' Study Group (in Room 6, 20 Buckingham Street, London, W.C.2), at 3.15 p.m.—Annual General Meeting.

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. Ludwig Koch: "Songs of Wild Birds and How I Recorded Them".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biochemist (basic grade) (with a B.Sc. degree, preferably with honours in biochemistry or chemistry, or an equivalent qualification)—The House Governor, General Hospital, Birmingham 4 (November 15).

Chemist (Senior Scientific Assistant) in the Central Laboratory, Chiswick, with responsibility for section concerned with wide variety of analytical and investigational work other than metals, fuels, lubricants and paints—The Staff Officer (F/EV 221), London Transport, 55 Broadway, London, S.W.1 (November 15).

Resident Assistant Lecturer in Agriculture at the Cumberland and Westmorland Farm School, Newton Rigg, Penrith, and for lecturing, demonstration and advisory work in the two counties—The Director of Education, 5 Portland Square, Carlisle (November 15).

Second Assistant Engineer (Chemist) (with first- or second-class honours degree in chemistry or associateship of the R.I.C., with emphasis on physical and inorganic chemistry) in the Generation Operation Branch at Bankside—The Director of Establishments, British Electricity Authority, British Electricity House, Winsley Street, London, W.1, quoting Ref. AE/297 (November 17).

Senior Tobacco Extension Officer (with a degree in agriculture, and wide experience in tobacco culture, particularly flue-cured Virginia, including curing, handling and marketing)—The Secretary, Southern Rhodesia Government, 429 Strand, London, W.C.2 (November 20).

Assistant Lecturer in Geology (with special qualifications in petrology and economic geology)—The Registrar, University College, Cathays Park, Cardiff (November 22).

Director of the Tasmanian Museum and Art Gallery—The Agent-General for Tasmania, 457 Strand, London, W.C.2 (November 29).

Assistant Lecturer (Grade III) in Physiology (Veterinary)—The Registrar and Secretary, The University, Bristol (November 30).

Lecturer in Economics at New England University College (University of Sydney), Armidale, N.S.W.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (November 30).

Senior Masters (honours graduates) of Science, Mathematics, and Arts/Languages, at Welbeck Abbey, Worksop—The War Office (C.5), Whitehall, London, S.W.1 (November 30).

Senior Research Officer (with an honours degree in pure mathematics, with postgraduate or other training in mathematical statistics; research experience is essential) to be in charge of the Statistical Research Division, and a Research Officer (with an honours degree in psychology, preferably with mathematics and statistics as ancillary subjects) in the Industrial Research Team, to carry out research in the applied psychological field in industry, in the National Institute for Personnel Research, Johannesburg—The South African Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2 (November 30).

Lecturer in Physiology at University College, Dundee—The Secretary, The University, St. Andrews (December 1).

Research Fellowships in Economic History and Economic Statistics, Australian History, Law, Statistics, including Mathematical Statistics, Geography, International Relations, and Pacific History—The Administrative Officer in the U.K., Australian National University, 27 Russell Square, London, W.C.1 (December 1).

Chair of Mechanical Engineering and the Chair of Electrical Engineering, in the University of Roorkee, India—The High Commissioner of India (General Department), India House, Aldwych, London, W.C.2 (December 31).

Abstractor (a degree in engineering or physics is desirable) for duties consisting mainly of abstracting and summarizing technical and scientific papers in shipbuilding, marine engineering, naval architecture, general physics and engineering, and also dealing with technical inquiries relating to published material in these fields—The Secretary, British Shipbuilding Research Association, 5 Chesterfield Gardens, London, W.1.

Assistant, Grade B (with a university degree in science) in the Department of Chemistry—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Assistant, Grade B (with honours degree in geology) in Geology—The Principal, Derby Technical College, Normanton Road, Derby.

Assistant Statistician to the Medical Research Council's Social Medicine Research Unit—Dr. J. N. Morris, Social Medicine Research Unit, Central Middlesex Hospital, Acton Lane, London, N.W.10.

Chief Hydrological Engineer in the Soil Conservation Section of the Ministry of Agriculture—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Chief Hydrological Engineer 404'.

Entomologist to carry out a survey of the tsetse areas of the Sudan and undertake research work—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Entomologist 2204'.

Graduate in Chemistry or Physics as Research Assistant in Chemical Engineering Department, to do research on flame propagation in gases—The Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7.

GRADUATE IN PHARMACY (with industrial experience) in the Department of Pharmacy—The Secretary, Royal Technical College, Glasgow.

LECTURER IN PHYSICAL CHEMISTRY—The Principal, Sir John Cass College, Jewry Street, London, E.C.3.

PHYSICIST (senior or basic grade) IN THE RADIOTHERAPY DEPARTMENT—The Group Secretary, Central Office, Nunnery Fields Hospital, Canterbury.

PHYSICIST (with honours degree) FOR WORK IN TECHNOLOGICAL DEPARTMENT involving investigations into friction and measurement and control of yarn tension—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

PROFESSOR OF ANALYTICAL CHEMISTRY—The Chairman, Department of Chemistry, University of Montreal, Montreal 26, Canada.

RESEARCH ASSISTANT PHYSICIST to undertake the development of a recording microspectrophotometer and the investigation of dichroism of biological crystallites—The Secretary to the Board, Royal Infirmary Branch, Bristol 2.

SENIOR EXPERIMENTAL OFFICER at the Ministry of Supply Trials Wing Outstation, Aberporth, South Wales, for duties mainly concerned with control of operation and maintenance of electronic instruments and supervision of technical work—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.401/52A.

SURVEYORS (university graduates with a degree, preferably with honours, in mathematics, physics, engineering, or geography, including geodesy) in the Colonial Survey Service and the Directorate of Colonial Surveys—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

INDUSTRIAL MANAGEMENT IN THE WELFARE STATE

IN its report for the year ending March 31, 1952, the Council of the British Institute of Management once again stressed the way uncertainty regarding future Government financial assistance handicaps the work of the Institute. The original five-year arrangement with the Government has now almost expired, and although the present Government has assured a deputation of its continued support of the purposes for which the Institute was established in 1948, the grant-in-aid of £50,000 eventually included in the Board of Trade estimates for 1952–53 is regarded as inadequate, notwithstanding the continuing growth of subscription income, to enable the Institute to carry out the full functions of a central institute of management. Since much of the Institute's work is of the nature of a public service to British industry as a whole, the Council makes a strong claim for a further and continuing contribution towards the cost of such service from public funds.

The completion of the merger with the Institute of Industrial Administration strengthens that claim, and it is also supported by the evidence in the reports of the Anglo-American Council on Productivity's teams on management accounting and on education for management. Elsewhere, the decisive contribution which management could make towards increasing productivity, and remedying the deficiency in Britain of men trained for management is widely recognized. It should be remembered, too, that when, in accordance with the recommendation of the Baillieu report six years ago the British Institute of Management was established, it was supported not only by Government funds but also by industry. The Council of the Institute believes that with even a fifty per cent increase in the present grant of £50,000 the Institute could meet the many and important demands now being made upon it.

What is possibly even more important is that the Institute should no longer be compelled to organize its work on a year-to-year basis. Such conditions are inimical to effective work in education and still more in research. The first fruits of the Institute's work in this latter field reinforce the claims of the Institute for the quite small sums which are required to place its work on an adequate and a permanent basis.

If the British Institute of Management's Field Research Group further develops its scrutiny of technical and managerial methods and skills and their adaptation to present requirements, it will be essential for the Institute to be assured of continued financial support. The value of a case study of an organization in its social environment as a complex indivisible unit has recently been demonstrated strikingly by the publication of a volume containing three such studies by J. F. Scott and R. P. Lynton. The Institute is not, of course, alone in making such investigations. Recent studies carried out, for example, by the Acton Society Trust, by the National Institute of Industrial Psychology or the Tavistock

Institute of Human Relations in association with the Human Factors Panel of the Committee on Industrial Productivity and by the Department of Social Science of the University of Liverpool, all emphasize the importance of such investigations and their bearing on productivity and the economic future of Great Britain.

The study of joint consultation in British industry published earlier this year (cf. *Nature*, 170, 254; 1952) noted a tendency for managers with high technical qualifications to pay insufficient attention to human factors in administration; nevertheless, it brought out the extent to which the whole problem of communication within industry is largely unsolved and that, while the responsibility for action and initiative may rest with management, all the faults do not lie on that side. New attitudes require to be developed on both sides. Dr. W. H. Scott's study* of human relations in three Merseyside firms largely corroborates the evidence obtained in the inquiry conducted earlier by the National Institute of Industrial Psychology's research team. This study, to which Sir George Schuster once again contributes a foreword, is an extension of work originally promoted by the Human Factors Panel. It provides further evidence that the working of a joint consultative system is extricably interwoven with, and conditioned by, the whole pattern of personal relations and informal structure in a particular firm, and by the pattern of deep-seated loyalties and suspicions which inevitably exist. No form of joint consultative machinery can accordingly fit every firm indiscriminately, and no system of joint consultation will work unless the total situation in the firm is right.

There is clear enough warning in Dr. Scott's book of the danger of attempting to create the right kind of co-operative spirit in industry by compulsory prescription of any standard form of joint consultative committee; but even more emphatically is that warning given by the Acton Society Trust's latest study, "The Worker's Point of View"†. This discussion of 'reporting back' based on a study in a coalfield gives a startling picture of the failure of the joint consultative machinery provided by statute, both to give employees an opportunity of having a say in the running of their firm or industry, and to supply them with sufficient background knowledge to ensure that their contribution is useful and relevant. In actual fact, so far from arousing a new sense of participation, the provision made under the Nationalization Acts has proved quite ineffective for both purposes. The dominant factor in the situation revealed by this study is not so much ignorance as the existence of an appalling range of positive misconception and misinformation. The very conditions in which joint consultation can function have still to be created.

To some extent this has already become apparent outside industry, through such incidents as the rejection by mine-workers of Italian workers. But the Acton Society Trust's study brings out clearly three factors, or rather attitudes, which dominate the whole situation: a persistent fear of the return of unemployment; a deep suspicion of all those in authority, who are thought to be idle or venal when not cruel or malicious; and a belief that the public regards the miner as an inferior type of human being and almost a social outcast. Joint consultation and the effective absorption of information are scarcely possible while such attitudes persist, and nothing less than an intensive programme of education and re-education on a national scale will serve. The practical problem is two-fold—whether from the point of view of joint consultation or morale; to provide more factual information, and to dispel these suspicions.

The Acton Society Trust does not suggest that there have been no failures to pass on effectively information which has been supplied; but it rightly insists on the necessity of restoring confidence in management—a point equally stressed in Dr. Scott's investigation. But it is the loss of human relationships in the nationalized industries that is responsible for much of the difficulty, and here, as appears more fully in Dr. Joseph Goldstein's study of the government of British trade unions*, the trade unions themselves must bear part of the responsibility. The question may fairly be raised whether, from the point of view of human relations, the whole administrative structure of some nationalized industries, such as the railways, is fundamentally wrong.

The picture revealed by the Acton Society Trust's study is disquieting, not simply from the picture of ignorance, misconception and misinformation which it reveals but still more because so often managements appear not to have thought out clearly either what employees should know or how to give them this information, and have made little attempt to put into effect a definite policy. Much trouble, it is true, has been due to failure on the part of members of consultative committees to pass on the information which has been given them. Even here, however the question may be raised whether management is entitled to think it has discharged its responsibilities when it has given information to these committees

That view is supported by Dr. Scott's study, which emphasizes the dependence of effective consultation not merely on the social relations existing in the factory but also on the extent to which management has taken the trouble to secure that the attitudes and behaviour of departmental managers and supervisor are in harmony with policy, and correlated with the employees' approval of both higher management and the general conditions existing in the firm. Like the earlier investigation of the National Institut of Industrial Psychology, his study emphasizes the way in which the pattern set by senior management, and in particular the higher executive, tends to be reflected throughout an organization. Moreover, both studie conclude that where management's leadership is paternal, employees tend to be concerned mainly with the personal advantages they can derive from joint consultation. They agree also that the status problems of representatives and the apathy of the rank and file are serious obstacles to successful joint consultation ; joint consultation tends to be more successful where it has been introduced by the modification of existing arrangements, such as management – shop steward procedures.

* The Government of British Trade Unions: a Study of Apath and the Democratic Process in the Transport and General Worke Union. By Dr Joseph Goldstein. Pp. 300. (London: George Alle and Unwin, Ltd., 1952.) 25s net.

Sir George Schuster, in his foreword to Dr. Scott's book, expresses his belief that university departments are specially fitted to conduct the type of research in this field which, both by its methods and personnel, inspires the confidence essential for enlisting the active interest and collaboration of those concerned. That belief is substantiated by the approach to this study indicated by Dr. Scott, and by the account he gives of the methods used. No claim is advanced that the results described are more than preliminary, or that they show more than the interdependence of the various sectors of social relationships in an industrial organization and the very limited contribution which the introduction of formal joint consultation can make to the improvement of industrial relations. Nevertheless, they do something more than stress the cardinal importance of real leadership in general. The problems which further work should seek to clarify in this complex situation are indicated. The characteristics of the behaviour of a variety of leaders, and the associated attitudes and behaviour of the subordinates for whom they are responsible, at various levels in the everyday industrial situation, require description. Again, while morale and productivity may be less closely linked than has often been suggested, the important outstanding problem here is to determine whether there is a particular type of social structure within which both high morale and high productivity co-exist.

We are, in fact, rapidly increasing our knowledge of the ways in which change may be achieved, and this only increases the importance of developing our systematic knowledge of the directions in which change should proceed. Dr. Scott rightly urges that a fuller understanding of the nature of effective leadership, and of the factors which mould the behaviour of leaders, is needed if our increasing knowledge of the procedures which will facilitate change is to be used to the best advantage. But those procedures will only be used with confidence as the directions which change should take become clearly defined.

Accordingly, studies concerning the community and the cultural milieu of leaders are specially important, and this is emphasized at one particular point where these studies of Dr. Scott, the National Institute of Industrial Psychology and the Acton Society Trust touch Dr. Goldstein's study of British trade unions. The two former remark on the way in which a good trade union – management relationship facilitated joint consultation, and Dr. Scott, recognizing further the complication which inter-union rivalry can introduce, notes that the attempt to solve such problems will require an analysis of the structure and functioning of the trade union movement such as Dr. Goldstein has, in part, attempted. Quite as explicitly, the Acton Society Trust recognizes that in this matter of communications and leadership the sole responsibility does not rest on management : there is the further more specific question of immediate interest to the unions themselves of how far industrial democracy can be made a reality except on a basis of good communications.

To this question Dr. Goldstein's story of apathy and the democratic process in the Transport and General Workers Union gives a very perturbing answer. His study shows that the lack of interest of the rank-and-file of the workers revealed by those studies of leadership and joint consultation in specific firms is paralleled in one of the largest trade unions of Great Britain. At the same time, he demonstrates beyond question the way in which both the method of conveying public information and the determination of what information is relevant are matters of vital and direct concern to the unions as well as to industry.

The unrealistic view of industrial democracy prevalent in the Union studied by Dr. Goldstein is probably the most disturbing feature of his book. The domination of the Union by a small group which may be quite unrepresentative has dangers which are obvious, though within the Union they appear not to be realized. To some extent that position is due to the very high proportion of members who are automatically deprived of the opportunity of holding any office by a rule which makes office conditional on membership in good standing for at least two years.

Dr. Goldstein's study lends support to the view that, while the rules and constitution of this Union make it in theory fully democratic, the apathy of the ordinary workers has converted it into an oligarchy liable to be captured and used for purposes alien to the wishes of the majority, notwithstanding that members are, in general, alert and inquisitive persons. 'Branch' activities have failed to develop within the membership the social skills that are best expressed in an individual's capacity to receive communications from others and to respond to their attitudes and ideas, so as to promote well-informed participation in the common tasks of the democratic co-operation of the Union.

Nothing could better express the connexion between the management studies already discussed and the trade unions than this conclusion of Dr. Goldstein. He recognizes that the Union has many great achievements to its credit, and that it has trained many leaders who have served the community well. What is lacking is that tradition of democracy, which only everyday experience, custom and practice can build within the Union, and Dr. Goldstein maintains that it is the responsibility of the Union to widen the scope of its appeal to the rank-and-file beyond the horizon of mere wage increases or the improvement of conditions at a particular factory.

Part of the importance of this study lies in its revelation of the plain fact that the Union has failed to secure the active interest of most of its members. To that extent the Union faces the same problem as industrial management faces in joint consultation, and the response of the Unions to that challenge cannot be a matter of indifference to industry or to the nation as a whole. The self-contained attitude of at any rate some trade unions is a barrier to the development of wider loyalties in keeping with the need of the times. That is not stated explicitly by Dr. Goldstein, but a short-sighted insistence on the maintenance of vested power is likely to be the biggest obstacle to the trade unions accepting their responsibility of training the individual, through democratic participation, to adapt himself intelligently to the ever-changing personal relationships created by the demands of democracy in a highly industrialized economy.

If the trade unions do not respond to that challenge, democracy itself is endangered, for in the long run they alone can supply the tradition of democracy which is required for the growth of industrial democracy. If they accept the challenge, they will, as all these studies show, be faced with problems of communication, consultation and co-operation essentially similar to those which management faces in industry. In that lies the final reason for continued and adequate support by the Government of the British Institute of Management. It is not simply that the Institute is already making valuable investigations in this field—and that Messrs. J. F. Scott and R. P. Lynton provide a substantial basis for confidence in this question of securing co-operation and loyalty. It is rather that the British Institute of Management, as an independent body, with which trade unions are already associated, as well as industry, is doing unique work. It provides opportunities for managers and trade union leaders to meet in an atmosphere free from negotiation, and to explore informally many problems that are of common interest. In consultation with the trade union advisory committee, it is considering the desirability of including the field of trade union structure and working as a part of management training. Only such an independent body, the staff and methods of which command confidence, is in a position to provide whatever disinterested advice the trade unions require when they address themselves to the task of adapting their organization to meet the new demands and problems of the social welfare State. No more foolish economy could well be imagined than to jeopardize the efficient working of a body which serves such well-attested needs.

PRESENT POSITION OF METEOROLOGY

Compendium of Meteorology

Edited by Thomas F. Malone. Pp. ix+1334. (Boston, Mass.: American Meteorological Society, 1951.) 12 dollars.

THE preface of the "Compendium of Meteorology" states that the purpose of the book is to take stock of the present position of meteorology, to summarize the knowledge won by research in recent years, and to indicate lines for future study and research. The "Compendium", in fact, gives a broad survey of the state of knowledge in 1950 of physical and dynamical meteorology, of methods of weather forecasting, and of some aspects of climatology, applied meteorology and meteorological instrumentation.

The book has been compiled primarily for the professional meteorologist and other specialists in atmospheric physics. It must be made clear for the benefit of any who may be misled by the title that it does not include a collection of climatological data, physical tables, or tables for meteorological computers. It is not, on the whole, a text-book for new students of meteorology. Some articles cover the whole of their particular subject in a way very useful to readers with little previous knowledge; but many articles are very compressed, cover relatively recent developments only, and assume a thorough acquaintance with the bases of the subject.

There are a hundred and eight articles written by a hundred and two authors assembled into twenty-five sections. A few articles are by two or more authors. Seventy-seven of the authors are now working in the United States, though many of these, such as J. Bjerknes, B. Haurwitz and H. G. Booker, are of European origin. Eleven authors are now working in Britain. The great majority of authors are internationally known experts in their respective fields. The majority of the articles conclude with a list of problems on which research is most urgently needed and with extensive bibliographies.

The titles of the sections are, with brief notes, as follows: composition of the atmosphere (one article, chemical composition); radiation (three articles); meteorological optics (three articles, includes physics of visibility); atmospheric electricity (six articles); cloud physics (seven articles, includes artificial stimulation of precipitation); the upper atmosphere (twelve articles, atmosphere above the tropopause); cosmical meteorology (two articles, relations between solar phenomena and terrestrial weather changes); dynamics of the atmosphere (ten articles, includes meteorological thermodynamics, turbulence, and atmospheric tides); general circulation (three articles, summary of observations as well as theories); mechanics of pressure systems (six articles, pressure temperature and wind structure of depressions and anticyclones); local circulations (four articles, sea breezes, orographic effects on wind, air currents of thunderclouds); observations and analysis (three articles, distribution of observing stations, methods of plotting and analysing weather charts); weather forecasting (nine articles, short- and long-period forecasting, vertification of forecasts); tropical meteorology (four articles); polar meteorology (three articles, one on the Antarctic is very comprehensive on the aerological side); climatology (six articles, applications of meteorological information in planning, past climates, microclimatology); hydrometeorology (two articles, application of rainfall data in water supply and control of river flow); marine meteorology (four articles, exchange of energy between air and sea, ocean waves); biological and chemical meteorology (three articles, distribution of biological organisms by the atmosphere, human bioclimatology, measurement of atmospheric composition and other chemical problems); atmospheric pollution (one article); clouds, fog, and aircraft icing (five articles); meteorological instruments (two articles, almost exclusively on instruments for upper-air observation); laboratory investigations (three articles, use of models in meteorological research); radio meteorology (four articles, radar cloud echoes, refraction of high-frequency electromagnetic waves, use of location of atmospherics in weather forecasting); and microseisms (two articles, causes of microseisms and their application in forecasting).

The book shows that, as is natural, the greatest progress has been made in those parts of meteorology in which experiment is possible. Experiments in cloud physics, stimulated by the scientific desire to understand the processes of condensation of water vapour and formation of precipitation, the attraction of artificial precipitation and artificial cloud dispersal, and the need to minimize ice accretion on aircraft have led to great progress in that subject. Development in radio apparatus has given the meteorologist much better instruments than before 1939 for examining cloud structure and measuring pressure, wind and temperature in the free atmosphere.

Though techniques have improved and the number of stations increased, we learn that the accuracy of observation of some elements is not high enough for numerical forecasting and that over much of the equatorial regions and southern hemisphere stations are too sparse for scientific needs. Disappointment at the failure of the increase in the amount of information to provide more accurate forecasts of general weather is strongly expressed. The writers on synoptic meteorology and the general circulation are clear that more effort needs to be devoted to study of the circulation as a whole and to basic research in meteorological physics, at the expense of study of local circulations and development of empirical forecasting techniques.

The articles on meteorological dynamics and thermodynamics provide excellent summaries of these subjects and show very clearly their immense difficulties. The differential equations can only be solved for simplified states of steady motion or for first-order perturbations from those states, and the observed effects are given in the equations as the relatively small differences between two large terms the values of which are not known with sufficient accuracy for calculation of the differences. In his article on numerical prediction J. G. Charney is hopeful about allowing for radiation and condensation of water vapour but pessimistic about the turbulent transfer of heat and momentum.

At the end of his article on the forecast problem, H. C. Willett calls for the establishment of an international centre for global meteorological research. In this connexion it is of interest to see that the first number (April 1952) of the *Bulletin of the World Meteorological Organization* shows that attention is being given to this proposal. One of the features of the developments of the past fourteen years has been the growing realization of the value of meteorological knowledge in civil and military planning and in the control of industrial and agricultural processes. The articles by C. S. Durst, H. E. Landsberg and W. C. Jacobs, R. Geiger and E. W. Hewson on these matters deserve study by planners, engineers and agriculturists as well as meteorologists.

Considered as a picture of developments since 1939 the book is very complete, and there seem to be few omissions. More might have been said on condensation trails in the articles on cloud physics; and the subject of turbulence in clear air at great heights, to which much effort has been devoted during the past five years, is not mentioned. Very few misprints have been noted. The type and illustrations are very clear and the binding good. The editors have evidently taken much care to ensure uniformity of notation in the mathematical articles. The index contains about twelve hundred entries and seems very complete.

Meteorologists and all to whom meteorological knowledge is important will be grateful to the American Meteorological Society and the Geophysics Research Division of the United States Air Force, which supported the preparation in financial and other ways, for the production of this magnificent book.

THE WORLD OF TOUCH

Psychology and Art of the Blind

By Prof. G. Révész. Translated from the German by Dr. H. A. Wolff. Pp. xxiv+338. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1950.) 42*s*. net.

As the title of Prof. G. Révész's book seems to suggest, there are here really two books combined into one. The first deals with the fundamental theory of haptics ("the impressions conveyed by the tactile and kinematic sense"); the second deals with the æsthetic experience in haptic perception and with the creative activity of the blind. The work as a whole opens up a field of investigation for haptics comparable in its way with the fields of optics and acoustics. Besides being an important original contribution to psychology, it will doubtless be of considerable interest to the student of æsthetics. Erudite, clear and critical, it carries the mark of the mature scholar.

The method employed is chiefly that of searching phenomenological analysis, supplemented where appropriate by experiment. The experiments are not of the 'stream-lined' variety favoured by many of the American psychologists. They are ingeniously simple and usually conclusive. The Continental tradition of phenomenology has never taken root in Britain, and among psychologists in the United States, with very few exceptions, the very word 'phenomenologist' is almost a term of abuse. Yet, on studying such a work as this, one cannot help feeling that psychology in these countries has been impoverished as a result. Only two of the eighty references cited by Prof. Révész are to American sources; and in a well-known symposium on perception (edited by Blake and Ramsey), published in the United States in 1951, more than five hundred references are cited; but Prof. Révész does not appear among them, although he has devoted a large proportion of a long and distinguished career to research on perception. These signs are disturbing.

One of the main conclusions reached by Prof. Révész involves a rejection of the alleged universal applicability of *Gestalt* principles to all modes of perception. It had been more or less tacitly assumed that the principles that are probably valid for vision hold also for touch, although the world of touch has been left almost unexplored by the *Gestalt* theorists. Prof. Révész argues that haptic and optic space are autonomous, and that the first is just as real psychologically as the second. The world of those born blind is just as spatial as the world of the sighted but in a phenomenologically different way. In haptic space we proceed from structure to form; in visual space we proceed from form to structure. Apprehension of form means the appreciation of a unity of elements fused in a total impression. Apprehension of structure means consciously acquiring knowledge of the spatial and temporal relations of the perceived object. Prof. Révész derives a number of principles which he believes govern haptic perception in a distinctive way.

Much of the second part of the book is taken up with a careful study of the life-histories and artistic achievements of a number of blind sculptors. Here one must pay a tribute to the immense effort expended by the author in collecting and checking his data. He concludes that the æsthetic 'function' of the haptic sense is very limited. The blind are unable to apprehend objects as individual entities because haptic perception merely gives type images devoid of individuality. This may explain why they have no desire to finger objects of art or to learn details of their form and structure.

The foregoing indicates the kind of issue raised by Prof. Révész. The reader interested in almost any aspect of human perception or in the nature of æsthetic experience is bound to learn a great deal from his book. He had also better prepare himself to unlearn, because he will encounter a challenge to many of his preconceptions.

JOHN COHEN

TEXT-BOOK OF SILVICULTURAL SYSTEMS

Silvicultural Systems

By Dr. R. S. Troup. (Oxford Manuals of Forestry.) Second edition, edited by E. W. Jones. Pp. xv+216+43 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1952.) 25s. net.

TROUP'S "Silvicultural Systems", published in 1928, has long been recognized both as one of the best forestry text-books in the English language and the best survey in any language of the subject with which it deals. Changes in the methods of handling forests, however desirable, can only be a very slow process, as variation in future treatment is unavoidably largely circumscribed by what has been done in the past. A consequence of this fact is that although changed practices inevitably become necessary with increase of experience and the progress of knowledge, a book such as this does not quickly become out of date. It is therefore not surprising that even after twenty-four years the editor of the new edition finds that he can accept almost unchanged the greater part of the text, and that, apart from a few relatively minor amendments, changes in view and in practice can mostly be dealt with in an additional final chapter. Dr. E. W. Jones has among British foresters an unrivalled knowledge of the silviculture and silvicultural practices of western Europe, derived from repeated visits, particularly to France and Switzerland, and he has also first-hand knowledge of some of the silvicultural problems of tropical forests. As, also, he was on Troup's staff teaching silviculture and carrying out research in the subject, he was obviously in an exceptionally good position to bring Troup's book in line with current thought and practice.

In his preface, Dr. Jones enumerates the main changes he has made, and, except for modifying Troup's rather unqualified acceptance of the view that the selection system with all-aged crops gives timber inferior to that obtained with the more or less uniform (even-aged) crops, it is clear that his original contribution is concentrated in the new Chapter 20, "Developments of the Last Twenty Years". This is, indeed, a masterly and valuable summary of recent trends of thought in this field. Dr. Jones, man of science that he is, is very careful to keep in view the economic and practical considerations that must always play a large part in choosing between possible alternatives, and I only disagree with him in his reluctance to accept the view that supervision of uneven-aged forest is more difficult than that of more or less even-aged forests worked under the other systems; above all, when the technical standard of the staff is not first-class.

This chapter brings out the greatly increased importance now attached to the maintenance of soil fertility, leading to a growing preference for less regularity both in age and size, and in species, and to the maintenance of the canopy, avoiding clear or very heavy fellings at all times. I miss at this point an assessment of the alleged merits of periodically admitting light and warmth to the soil, as there are certain conditions where the claim is made that undesirable accumulation of raw humus occurs without it; there are also conditions in the tropics where, with appropriate treatment, any damage that may ensue from such exposure may be more than compensated, both economically and silviculturally, by the quick establishment of a better new crop.

The second important point made is that there is now a demand for more freedom of action to adapt current work in the forest to economic changes, the nature and direction of which cannot be predicted. The feeling is very general that any operation which ties the hands of the forest manager for a long period is to be avoided: this is just one more of the reasons that is giving a bias in favour of woods of mixed ages and species. It might perhaps also have been noted how generally the stress has shifted from getting each area unit of a forest into a form fitting into a preconceived pattern under a silvicultural system, to getting it into a condition in which it is producing the maximum growth in quantity and quality. Attention is very rightly directed to the new factor of forest genetics to be kept in mind.

The five pages devoted to natural regeneration in tropical forests (pp. 200–4), together with p. 207 on the enrichment of tropical forest and scrub, while perhaps not entirely up to date, give a very fair idea of the position. The merits and demerits of clear felling with artificial regeneration, notably with agricultural crops ('taungya') as a method of quickly bringing a mainly unproductive forest into more or less full production, will appear to many to be of sufficient importance for fuller discussion; such drastic measures might quite well only be necessary once, when the forest is first brought under intensive working.

Dr. Jones has done forestry another considerable service in undertaking this revision, and it can confidently be predicted that the new edition will meet most requirements for another twenty years.

H. G. CHAMPION

Chemical Kinetics

By Prof. Keith J. Laidler. (International Chemical Series.) Pp. ix+408. (London: McGraw-Hill Publishing Co., Ltd., 1950.) 47*s*.

THERE has been a real need for a modern and intelligible book on chemical kinetics, and the present volume seems to provide such a book. It includes what may be called the classical material, in which it is pleasing to find that the contributions of those who laid the foundations of the subject are adequately recognized. The style is clear and concise, so that a large amount of information is presented in a readable form. Adequate references to literature are given, not confined to American publications.

All the important topics are covered, and special mention may be made of the clear accounts of the theory of absolute reaction-rates, which many students find difficult, and of chain reactions. Photochemical processes are included, and there is a good summary of polymerization. The experimental methods are briefly explained. It might have been mentioned on p. 34 that 'Pyrex' glass often gives anomalous results; the point is brought out later, but it could have been emphasized, since some apparent contradictions in results are due to this fact, as is mentioned on p. 52. There are useful short tables of results, and a selection of problems at the end of each chapter will be useful to students and teachers.

The chapter on catalysis is to some extent rather confused by the contradictory results of different workers, and in such cases it might have been better in an elementary work to wait until the subject is a little more clarified in such parts. They are more suited to a report than a text-book. All the same, it may be hoped that students beginning research may be stimulated by such contradictions to undertake work in the field. The book is one which can be warmly recommended as giving a modern and adequate account of its subject within its standard.

J. R. P.

Substances naturelles de synthèse

Préparations et méthodes de laboratoire. Collection publiée sous la direction de Dr. Léon Velluz. Vol. 3. Par J. Mathieu, P. Poirier, A. Petit et Dr. L. Velluz. Pp. 156. (Paris: Masson et Cie., 1951.) 1,750 francs.

THE third volume of this series follows the same plan as the two previous volumes (see *Nature*, 169, 169; 1952). It gives details, taken from current chemical literature, for the small-scale laboratory preparation of the following compounds: *dl*-glutamic acid from methyl acrylate and sodio ethyl acetamidomalonate (Snyder, Stockleton and Lewis, *J. Amer. Chem. Soc.*, 1945); *dl*-3:4-dihydroxyphenylalanine from piperonal (Barry, Mattocks and Hartung, *J. Amer. Chem. Soc.*, 1948); œstradiol from the acetate of dehydroandrosterone (Wilds and Djerassi, *J. Amer. Chem. Soc.*, 1946); *dl*-ornithine from acrylonitrile and ethyl acetamidomalonate (Albertson and Archer, *J. Amer. Chem. Soc.*, 1945); and thiamin (vitamin B$_1$) (Gravin, *J. Chim. App. U.R.S.S.*, 1943). There are many additional notes on the preparation of intermediates, and on a variety of topics connected with the syntheses, including the Michael reaction, aliphatic nitroso compounds, bromination of 3-ketosteroids, syntheses of equilenin and œstrone, the Stobbe reaction, cyanoethylation, the synthesis of pyrimidines and thiazoles, the preparation of alcohols from amines, and oxythiamine.

Two sections deal at some length with the preparation of thiazoles and benzthiazoles, and with the synthesis of α-amino-acids. These articles tabulate many thiazoles and amino-acids, with their methods of preparation and the relevant references. There is finally a short article on the determination of melting points, and the book is completed by a table of contents, and author and compound indexes to the experimental sections.

W. Baker

Treatise on Powder Metallurgy

By Dr. Claus G. Goetzel. Vol. 3: Classified and Annotated Bibliography. Pp. xxiv+899. (New York: Interscience Publishers, Inc., 1952.) 22 dollars.

THIS is the third, and last, volume of Dr. C. G. Goetzel's "Treatise" (see *Nature*, 168, 133; 1951), and its appearance crowns a magnificent achievement. It consists of a classified and annotated bibliography and comprises, with indexes, etc., 899 pages. After a short preface, with acknowledgments and a section on the use of the bibliography, there is a full contents table giving the sub-divisions of chapters and sections. The bibliography follows the same order and divisions of subject as that in the preceding volumes. The literature survey comprises 5,535 separate references, each accompanied by a short annotation indicating the main subject and sufficient to indicate the necessity or otherwise of further study. References are complete to January 1, 1950, and careful search has failed to disclose any important gap.

The patent index cites 6,330 patents, including American and British, and many French, German and other Continental countries. There is a complete subject index, and the very full name index differentiates between literature and patents by using Arabic numerals for the former and italic numerals for the latter.

Now that the complete treatise on powder metallurgy is available, it is possible to appreciate the magnitude of Dr. Goetzel's work and to assess, in part at least, the nature of the contribution he has made to all present and future workers in this field. There can be no question that this "Treatise" will provide the standard work on the subject for many years to come and will be indispensable in every reference library on metallurgy.

Preparation of Organic Intermediates

By Prof. David Allen Shirley. Pp. x+328. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1951.) 48*s*. net.

ALTHOUGH the range of organic chemicals offered by chemical manufacturers is ever increasing, more often than not a certain intermediate which is needed for a synthesis is not available, and the laboratory worker has to resort to its preparation. Usually, he first refers to "Organic Syntheses" to see whether preparative details are given in one of the several volumes of the series. If not, he has to search the original literature and often make a judicious selection. This book contains specific preparative information on more than five hundred useful organic compounds. The preparations listed are all taken directly from the literature, but the author is to be congratulated on the selection of compounds included and the preparative methods adopted. The criteria which determined his choice of intermediates were as follows: the compounds are not available commercially or, if available, are relatively expensive; they are useful intermediates for the synthesis of other chemicals, or their method of preparation serves as an example of a generally useful type of organic reaction; the starting materials are commonly available (in the United States) or, if not, their preparation is described in "Organic Syntheses" or elsewhere in the book.

All the preparations are on a convenient and useful laboratory scale. The inclusion of some catalyst preparations and certain precautionary notices concerning hazards are commendable features. In addition to a molecular formula and general index, there is a "type of reaction" index which is valuable and which serves to indicate the wide range of reactions covered.

This book is a worthy companion volume to "Organic Syntheses". J. IDRIS JONES

Artificial Fibres

By R. W. Moncrieff. Pp. x+313. (London: National Trade Press, Ltd., 1950.) 25*s*. net.

FIBRES from groundnuts, others from seaweed, fibres long known such as those from the cuprammonium process, celanese and viscose, others more modern such as nylon, 'Terylene', and vicara, lesser-known ones such as those made from glass or from polythene; fibres manufactured, spun, woven, stretched, regenerated, dyed, their strength tested; fibres examined, analysed, identified and their molecular structure investigated; staple fibres, lustrous fibres, anti-crease fibres; all are described or discussed by the author—himself a master craftsman—in this interesting and informative book.

Besides being clearly and singularly well written, the book is made additionally attractive by its 112 illustrations, many of which are in half-tone. The thirty-one chapters are grouped to make five parts severally headed as follows: the structure and properties of fibres; regenerated cellulosic and alginic fibres; regenerated protein fibres; synthetic fibres; and processing. The greater part of the text will be easily understood and enjoyed by the ordinary reader. The sections appealing only to the expert are well done and supported by abundant references to the literature. A perusal fully bears out the publisher's claim that the book affords a thorough up-to-date survey of modern synthetic fibres, and it should appeal to all in any way concerned with these new and promising materials.

The Hardness of Metals

By D. Tabor. (Monographs on the Physics and Chemistry of Materials.) Pp. ix+176. (Oxford: Clarendon Press; London: Oxford University Press, 1951.) 15*s*. net.

STANDARD text-books satisfactorily describe the various techniques of hardness testing and critically discuss their relative advantages and disadvantages in practice. They do not, however, provide any clear understanding of what is meant by 'hardness'; nor do they explain the hardness behaviour of metals in terms of any of the well-understood physical properties. The omission is rectified by the book under review. Over a period of several years the author has studied the problems of contact between solid surfaces and, finding the existing theory of deformation by indenters quite inadequate, he has proceeded to build up a satisfactory treatment in terms of the formal theory of plasticity using only very simple mathematical methods. No reader can fail to be impressed by the thorough way in which this has been done, for light is thrown on almost every aspect of hardness behaviour. Meyer's Law is derived from the stress–strain curve; the relationship between Brinell hardness and ultimate tensile strength is explained, and many empirical relationships deduced from practical experience are given a physical basis.

Dynamic or rebound hardness and the factors determining the area of contact between solids are discussed in the final two chapters.

This book is clearly written and illustrated and can be warmly recommended to all those who are interested in the hardness of metals. It is without doubt the most important work on the subject to have appeared for many years.

A. G. QUARRELL

The Old Place

By C. C. Vyvyan. Pp. 190. (London: Museum Press, n.d.) 15*s*. net.

IN an age of ever-increasing statistics and sociological studies there is a danger that the history of our times may become intelligible only to those of our successors who have familiarized themselves with the requisite techniques. Yet shades of emphasis and the nuances of everyday life are still difficult to express mathematically and need the eye and expressive powers of the artist before they can be transmitted to others elsewhere. In "The Old Place", Miss C. C. Vyvyan would be the last to claim that she had written a precise account of what the Second World War had meant to those who lived in large country homes. She could claim to have recorded faithfully her part in the struggle to 'keep up' at least some of the standards of one fine old country house, and especially its garden. This simple account of a determined and not unsuccessful effort to restore the house and garden to a state of beauty after years of requisition by military and other authorities is one which was worth the telling; it deserves readers, now and hereafter.

The British Pharmaceutical Codex, 1949

Supplement 1952. (Published by direction of the Council of the Pharmaceutical Society of Great Britain.) Pp. xii+148. (London: Pharmaceutical Press, 1952.) 25*s*. net.

THE continual appearance of new drugs makes it difficult to keep the books of reference up to date. The "British Pharmacopœia" of 1948 was followed by an addendum in 1951, and the "Codex" of 1949 is followed by a supplement in 1952. This supplement contains new general monographs, dealing with twenty-two drugs now officially described for the first time in Great Britain, and fourteen drugs already described in the addendum to the British Pharmacopœia. There are also fourteen old monographs which have been amended because the drugs appeared in the addendum.

The new drugs include amidone, aureomycin, cyanocobalamin (vitamin B_{12}), dapsone, decamethonium, diethylcarbamazine (Hetrazan), gallamine (Flaxedil), gammabenzene, lucanthone (Miracil *D*), mephenesin, solapsone (Sulphetrone) and troxidone (Tridione). It is good to have official standards and names for all these drugs, and reliable paragraphs on their actions and uses. The Codex Revision Committee is to be congratulated.

REACTIVITY OF FREE RADICALS

FARADAY SOCIETY DISCUSSION IN TORONTO

THE first full meeting of the Faraday Society held outside the United Kingdom took place in Toronto during September 8–9. Owing to the generosity and hospitality of Canadian chemists, a strong party of British chemists was able to participate in the meeting and to see something at first hand of Canadian achievements in chemistry during visits to university, government and industrial laboratories. The subject of the discussion, "The Reactivity of Free Radicals", was deliberately chosen to focus attention on the more quantitative aspects of the chemistry of free radicals. The Faraday Society has already held a number of discussions directly concerned with radicals and having a considerable bearing on such specialized subjects as oxidation, polymerization and related phenomena. In 1947 the discussion on labile molecules marked the opening of the quantitative phase. Here the principles of determining the absolute reactivity of radicals became apparent, and the complete chemistry, as well as the kinetics of reactions, began to develop. In five years extremely rapid progress has been made, and the present discussion covered the whole field, with the exception of the chemistry of polymer radicals, so that it was possible to appreciate from the papers the present position of what used to be a rather nebulous and highly controversial part of physical chemistry. The character of the discussion naturally took special notice of the important developments in Canada in this field; in fact, it was particularly appropriate that the discussion might in this way pay a tribute to the progress of Canadian physical chemistry. The Canadian interest centred mainly on gas phase reactions, while the British contributions were more concerned with liquid phase phenomena. Some measure of Canadian achievement may be found from the fact that half the papers originated from the western side of the Atlantic.

Perhaps the more striking feature of the papers presented to the meeting is the variety of methods that can be brought to bear on the problem of radical reactivity. The conventional kinetic approach, namely, the effect of measurable variables like concentration, temperature and intensity of light on the rate of reaction, has been supplemented by quite independent methods, so that the rather tentative conclusions about mechanism devised from kinetics may be much more firmly established and the reality of the existence of radicals proved beyond all doubt.

One of the most striking new methods is flash photolysis (R. G. W. Norrish and G. Porter). Here an intense flash of radiation of short duration is projected into a reaction system, and, if radicals are formed, their concentration is so remarkably high that their ultra-violet absorption spectra may be recorded, with the great advantage of certain identification. Furthermore, the variation of concentration with time may be followed by suitable modification of the apparatus so that velocity coefficients can be determined in the most direct manner possible. For example (G. Herzberg and D. A. Ramsay), it has been known for some time that ammonia undergoes primary photolysis to hydrogen atoms and, it is suspected, amine radicals. Now, with flash photolysis, the existence of the amine radical shows up in its absorption spectrum. Further confirmatory evidence comes from observations on ammonia labelled with nitrogen-14. With the identification of the spectrum of NH_2, the so-called α-bands of ammonia which appear in discharges through ammonia, in ammonia flames and even in comets, can now be ascribed to a well-defined amine-emitter. The flash photolysis method is particularly useful in the study of explosions, for a photochemically active flash is so short in duration that the heating of the system occurs adiabatically and may easily reach and exceed the ignition temperature of an explosive mixture. Thus a new and controllable means of initiating explosions becomes available; but far more important is the fact that the nature of some of the radicals and the variation of their concentration with time may be followed throughout the short period of reaction. For example, with acetylene–oxygen mixtures sensitized by nitrogen dioxide, OH, CN, C_2 and CH radicals can all be observed simultaneously, and controversy as to the nature of these active intermediates at once stilled. Another application of the method makes it practicable to study photochemical reactions that do not ordinarily take place. If chlorine and oxygen are illuminated nothing happens, but by flash irradiation the hypochlorite radical can be observed and its reactions readily followed (G. Porter and F. J. Wright).

Another equally valuable but difficult technique consists in introducing a representative sample of a reacting mixture into the ionization chamber of a mass spectrometer and detecting any radicals present, owing to the fact that the ionization potentials are smaller than those of the molecules from which they were derived. The appearance potential, mass number, and the magnitude of the positive-ion current in sufficiently simple systems serves to identify the radicals. The first experiments with this method were essentially qualitative in nature, but now quantitative information about the efficiency of radical production is becoming available (F. P. Lossing, K. U. Ingold and A. W. Tickner). For example, in the primary decomposition of ethylene oxide each molecule gives rise to 0·6 methyl radicals, and with propylene the figure is down to 0·36. This promises well for the elucidation of the primary step in thermal transformations and therefore supplements the evidence from purely kinetic sources.

Although new methods yield new information about radical reactivities, there is much to be done by the older methods, provided sufficiently simple systems are investigated. For example, in the attack by methyl radicals on hydrogen molecules, experiments with all the deuterated varieties of the entities concerned show that the nature of the molecule rather than that of the radical determines reactivity (T. G. Majury and E. W. R. Steacie). Again, the production of atomic hydrogen by means of a hot tungsten filament in a flow system has resulted in a much clearer picture of the mechanism of attack on the ethane molecule. There seems to be little doubt that dehydrogenation is the first step, followed by the interaction of atomic hydrogen with the ethyl radical to yield two methyl radicals, the reaction being completed by the hydrogenation of the methyl radicals (M. R. Berlie and D. J. Le Roy). Another convenient way of generating atomic hydrogen consists in the photodecomposition of hydrogen sulphide thus :

$$h\nu + H_2S = H + SH.$$

The hydrogen atoms either decompose another molecule of hydrogen sulphide or interact with an olefine added to the system. By this competitive method the relative reactivities may be obtained. With paraffins the hydrogen atoms merely abstract hydrogen atoms, but by using deuterium sulphide the ratio HD/D_2 that is found gives a measure of the competition of the process involved (B. de B. Darwent and R. Roberts).

In the photolysis of complex polyatomic molecules like biacetyl, there is plenty of evidence of initial fission into acetyl radicals. Complications immediately arise when such radicals not only undergo further decomposition but, in addition, attack biacetyl. Precise quantum-yield measurements coupled with complete analysis of the reaction products can go a long way to obtaining the sequence of radical reactions involved. Such an analysis is normally extremely tedious, but by mass spectrometry the quantum yields for the production of all the molecules are readily measured so that a much more reliable scheme may be constructed (F. E. Blacet and W. Bell). When radicals from ketones (for example, diethyl ketone) are liberated in the presence of oxygen, the character of the reaction changes completely because of the rapidity with which oxygen adds on to the ethyl radical. Even at room temperature short chains are propagated in such a mixture. Instead of the radical yielding carbon monoxide, the final product of attack is carbon dioxide (A. Finkelstein and W. A. Noyes, jun.). Sometimes it is possible to choose a molecule for photochemical studies in such a way that only one of the radicals produced is sufficiently reactive to require study. Trifluoromethyl iodide is a case in point. The iodine atom can be photolysed off in the gas phase, leaving the trifluoromethyl (CF_3) radical for study. Measurement of quantum yield gives the surprisingly low value of 0·02–0·13, which apparently is mainly due to a fast back-reaction between the two entities concerned which can be suppressed to some extent if the trifluoromethyl radical reacts with an added molecule sufficiently rapidly (J. R. Dacey).

The nature of active nitrogen has been the cause of violent debate for forty years. In this discussion it has been admitted as a free radical mainly on the basis that it will attack olefines and hydrocarbons—the olefines faster than the paraffins, hydrocyanic acid being the main product. This leads to the strong suspicion that atomic nitrogen is the source of the activity, and this is supported by the fact that absorption lines in the vacuum ultra-violet spectrum due to atomic nitrogen can be identified (C. A. Winkler and H. I. Schiff). The long-continued glow is, however, difficult to understand on this assumption, since the atoms ought to disappear quite quickly even in pure nitrogen. Another kind of discharge, in water vapour in a flow system, can give rise to production of up to 50 per cent hydrogen peroxide in a liquid-air trap, thus demonstrating that hydroxyl radicals combine at low temperatures. When the contents of such a trap are warmed, first hydrogen and then oxygen is evolved, and water and hydrogen peroxide remain. How these gases are held in the cooled material is a matter not yet satisfactorily settled (P. A. Giguère, E. A. Secco and R. S. Eaton).

Nitric oxide has long been used as a retarder of gas-phase radical reactions in order to estimate chain-lengths. Under suitable conditions nitric oxide is a supporter of the combustion, in flames, of hydrogen, ammonia and hydrocarbons (G. K. Adams, W. G. Parker and H. G. Wolfhard). Although the results are preliminary, these studies open up another unexplored field of radical chemistry. Another inhibitor of chain reactions—lead tetraethyl—is now supposed to act through the medium of lead oxide (G. H. N. Chamberlain, D. E. Hoare and A. D. Walsh).

The discussion on processes in the liquid phase revealed a similar broad approach to the reactivity of radicals. There is as yet very little evidence about the behaviour of the same radical in both the liquid and gas phases, and thus a direct connecting link is missing. At present, the kinetics of liquid-phase radical reactions are treated as if they were gas-phase reactions in regard to the dynamics of collisions. On the whole, the analogy with gases works well enough but occasionally difficulties appear which demonstrate that the analogy breaks down. Much of the information about liquid-phase radical chemistry is derived from studies in addition-polymerization, but this topic was excluded to make room for a discussion of other radical reactions. Photosensitizers are extensively used to initiate radical reactions, and the elucidation of mechanisms is important. Therefore studies on the photo-oxidation of anthracene (E. J. Bowen and Miss K. K. Rohatgi) and of the photochemistry of anthracene dissolved in carbon tetrachloride yield a great deal of information concerning the interaction of electronically excited molecules with reactive substrates. The dehydrogenation of aldehydes is an essential step in the oxidation of these molecules. The resultant radicals do not in general undergo decarbonylation. Similar dehydrogenation may be brought about by the radical $Me_2C(CN)$, but not efficiently. Thiols, however, enormously increase the rate of dehydrogenation and are regenerated in a cyclic process, so much so that the aldehydes are readily decarbonylated to the corresponding hydrocarbons (W. A. Waters and K. E. J. Barrett).

The decomposition of hydroperoxide provides another means of generating radicals. Normally, such a decomposition is a unimolecular process ; but thi does not always happen, for the reaction in certain circumstances becomes bimolecular, kinetically, though radicals still form a primary product of decomposition (L. Bateman, Mrs. H. Hughes and A. L. Morris). In the presence of certain oxidizable substances hydroperoxides can be induced to decompose very much more rapidly than on their own. This is industrially important, for it enables polymerization to be carried out at lower temperatures. Poly-ethylene polyamine of the general formula $H_2N(C_2H_4NH)_xH$ are particularly effective if they are associated with ferrou iron as a complex (R. J. Orr and H. L. Williams). Many such organic reactions are apparently simple stoichiometrically, but the mechanism is very much more complex. Such an example is the direct addition of trichlorobromomethane to vinyl acetate or cyclohexene. Kinetic methods, however, make it possible to analyse the mechanism completely and to get quantitative data about the reactivity of trichloromethyl radicals and derived radicals such a $CCl_3.CH_2.CH(OCOCH_3)$, which data have important application in many related fields (H. W. Melville, J. C. Robb and R. C. Tutton).

It has been known for many years that heavy metal ions which are present even in small traces can accelerate radical reactions like oxidation. These heavy metal ions, such as cobalt, act as true catalysts by means of electron transfer reactions with hydroperoxides, for example, giving rise to radicals which then initiate reactions. A typical reaction is $M^{2+} + R\text{OOH} \rightarrow M^{3+} + R\text{O}\cdot + \text{OH}^-$. If M is cobalt, then Co^{3+} is so powerful an oxidizing agent that it decomposes water as $\text{Co}^{3+} + \text{OH}^- \rightarrow \text{Co}^{2+} + \text{OH}\cdot$. Actual reactions are usually much more complex, but kinetic methods are leading to a complete elucidation in some cases (C. E. H. Bawn). With another related system—ferrous iron and hydrogen peroxide—benzene may be readily oxidized at room temperature with the production of phenol and diphenyl resulting from the dimerization of phenyl radicals produced by the dehydrogenation of benzene with hydroxyl radicals. Again, the precise mechanism yields to kinetic analysis (J. H. Baxendale and J. Magee). Sometimes it is not possible to perform a complete analysis, as, for example, in the attack of a phenyl radical on a variety of substituted benzene derivatives. However, it is possible to get relative rates of attack. In this system there is, fortunately, some guidance from the quantum-mechanical theory of aromatic structures (D. H. Hey and G. H. Williams). This guidance is lacking in the interpretation of most radical reactions. In fact, this lack of theory in radical reactions is a serious barrier to further progress. There is an increasing and exact body of experimental data available, and there is as yet very little in the way of fundamental explanation of even relative reactivities, apart altogether from absolute reactivities.

In many radical reactions large radicals are produced which may break up thermally before the next reaction-step takes place. Decarbonylation, referred to above, is an example, whereas degradation of hydrocarbon radicals and polymer radicals is well known. The methods of dealing with yet another complication were also considered in the discussion (F. S. Dainton and K. J. Ivin). More complicated still are those systems in which heterogeneity exists at first or is produced during the course of a reaction. This can happen in some oxidations and in polymerizations such as styrene and maleic anhydride, and leads to a state of affairs where homogeneous reaction treatment is not adequate to cope with the situation (C. H. Bamford and W. G. Barb).

H. W. MELVILLE

THE HUMAN BLOOD GROUPS

By DR. F. STRATTON

Director of the Regional Blood Transfusion Centre, Manchester

THE Medical Research Council has issued a revision[1] of its Memorandum No. 19, on "*Rh* Blood Groups and their Clinical Effects". Some of the sections have been considerably revised but others have only minor alterations.

The *Rh* system has been one of considerable interest and stands, as it were, at the crossroads between the older *ABO* and *MN* blood groups and those that have been discovered more recently. With the investigation of the *Rh* system the complexity of the human blood groups was realized, and the significance of their clinical effects more appreciated and understood.

Blood group systems	Year of discovery	Erythrocyte antigens	Principal types	Frequency of principal types (per cent)	Known anti-bodies
ABO	1900 1911	$A_1A_2\,B$	$A_1B\;A_2B$	3	anti-A
			$A_1\;\;A_2$	40	anti-A_1
			B	8·5	anti-B
			O	48·5	
MN *S s*	1927 1947	$MN\;Ss$	MS	20	anti-M
			MNS	28	anti-N
			Ms	8	anti-S
			MNs	22	anti-s
			NS	7	
			Ns	15	
P	1927	P	P-pos.	77	anti-P
			P-neg.	23	
Rh	1940/5	$CcDdEeC^w$	cde/cde	15	anti-D
			cDE/cDE	2	anti-C
			CDe/CDe	17	anti-E
			cDE/cde	11	anti-c
			CDe/cde	32	anti-e
			CDe/cDE	12	anti-C^w
			cDe/cde	2	
Lutheran	1945	Lu^a	$Lu(a+)$	8	anti-Lu^a
			$Lu(a-)$	92	
Kell	1946	$K\;k$	KK	0·2	anti-K
			Kk	10	anti-k
			kk	90	
Lewis	1946	$Le^a\;Le^b$	$Le(a+b-)$	22	anti-Le^a
			$Le(a-b+)$	70	anti-Le^b
			$Le(a-b-)$	8	
Duffy	1950	$Fy^a\;Fy^b$	$Fy^aFy^a\;Fy^aFy^b$	66	anti-Fy^a
			Fy^bFy^b	34	anti-Fy^b
Kidd	1951	Jk^a	$Jk(a+)$	77	anti-Jk^a
			$Jk(a-)$	23	

The accompanying table shows the commoner human blood groups, with English frequencies[2]. The *ABO* frequencies are Manchester ones. Including the *Rh* system, six of the series have been discovered during the past ten years.

Blood groups are due to the presence of antigens on the surface of the red blood cells. These erythrocyte antigens when injected into man or animals produce, sometimes in one, sometimes in both, a specific antibody. This antibody is used for the detection of the blood group, and, therefore, the determination of a new blood group antigen depends upon the finding of a particular antibody and the establishment of the fact that it determines a new antigen present on the surface of the red cell.

The blood groups listed in the table are the commoner ones, but others have been found which have been aptly labelled by Levine[3] as 'private' blood groups, that is, the positive or negative reactions are found only within a particular family, such as the *Miltenberger* group which he described and the *Levay* group of Callender and Race[4]. Another antigen is the Tj^a antigen of Levine[3], which is so far known to be absent only from the red blood cells of persons whose sera contain the antibody, or from their immediate relatives.

The antibodies which are used for the typing of blood groups are either human or animal in origin. The human antibodies may be regularly occurring ones, such as anti-A and anti-B antibodies, with which Landsteiner[5] first discovered the *ABO* groups at the beginning of this century. These are the only regularly occurring blood group antibodies in human blood. Other blood group antibodies do occur naturally in human serum, that is, not as a result of immunization; but their occurrence is irregular and their presence atypical. Such antibodies are the anti-P which detects the P blood group, and the *Lewis* series of antibodies which detect the antigens of the complicated *Lewis* blood group system. Immune human antibodies have lately been used for the discovery of the more recent blood groups; for example, the *S* sub-groups of the *MN* system and the *Kell*, *Duffy* and *Kidd* groups. These immune antibodies have resulted either from repeated immunization due to blood transfusion, or to the iso-immunization which occurs sometimes during pregnancy, or to a combination of both these factors.

Animal antibodies have been used for a long time for *MN* typing, and the *Rh* system itself was first discovered by Landsteiner and Wiener[6] using animal anti-*Rh* serum. Nowadays, however, with the exception of the *MN* groups, most blood grouping is done using natural or immune human antisera.

The great increase in the discovery of human blood groups in the past few years has been due partly to the occurrence of greater chances of immunization (in the main caused by the increase in blood transfusion therapy) as well as to the realization that pregnancy may cause iso-immunization, and partially to technical advances. Had no technical advances been made, it is quite possible that many of the newer blood groups would not have been discovered, since, in spite of the presence of the antibodies, these would have remained undetected. This may well mean that there are other blood group antigens present on human erythrocytes which may be detectable when suitable technical methods are available. It is probable, too, that more attention will be given to the study of the antibodies themselves, since it is the ability to recognize the antigen – antibody reaction on which substantially depends the recognition of new blood groups. Many different antibodies do not necessarily mean many different heritable agglutinogens.

Another interesting study has been that of the frequency of the various blood groups in the different races of man. It was known previously that the *ABO* and *MN* groups occurred in the different races of man with slightly different frequencies, but when the newer blood groups were examined it was found that these were widely different. Negroes probably have greater differences from the White than many other races; for example, in the *Rh* system one type (*cDe*/*cde*, Rh_0r) has a frequency of about 2 per cent in the English population but about 46 per cent in the Negro population[7]. Again, in the Chinese[7], *Rh*-negative persons are almost unknown, whereas in England they number about 17 per cent of the population; similarly, in studies of South American Indians[8], the *Duffy* blood group is always found to be negative, whereas in White populations 65 per cent are *Duffy*-positive. In North-West Pakistan, 91 per cent of the population are *Duffy*-positive[9].

These are very remarkable differences, but other interesting things have been discovered. It has always been realized that the *Rh* system was one of great intricacy; but for some time it had been thought that the *ABO* and *MN* groups were, compared with this, relatively simple ones. Study of these groups in the different races of man, however, has revealed that they are more complex. In the *MN* groups the *S* sub-groups were found in 1947; Landsteiner, Strutton and Chase[10] originally described a different type of *M* in Negroes, and Ikin and Mourant[11] have described another variety of *M* which is probably different from the former. In the *ABO* groups it has been found that certain group *O* Indians have, in their sera, an antibody which had always previously been considered to be of an anti-*O* variety[12]. This obviously does not fit our present ideas, and reveals further blood group characters within the *ABO* groups. Thus we see that whereas previously the complexity of the human blood groups was realized from serological and genetical studies, latterly their complexity has been further revealed by studies of the blood groups in the different races of man.

Soon after the discovery of the human blood groups, it was found that they were inherited and that the erythrocyte antigens were determined by allelomorphic genes. The inheritance was according to the Mendelian laws. Blood typing is generally possible; but genotyping may be possible only in certain cases. Genotyping is desirable since it is more accurate, and it is often necessary to know whether a person is homozygous or heterozygous with respect to a particular agglutinogen. If this is to be known, it is not only necessary to have the antibody of the particular blood group agglutinogen but also the antibody of its allele or, if the system is complex, the numerous antibodies of the system. Blood typing is sometimes actual genotyping—for example, in the *MN* system—in contradiction to the *ABO* groups where typing is not genotyping. In some of the more recently discovered groups, such as the *Kell* and *Duffy* systems, it was at first possible to group a person as *Kell*-positive or *Kell*-negative, or *Duffy*-positive or *Duffy*-negative; but later, other antibodies have been discovered to their alleles, the one in the *Kell* system being referred to as an 'anti-*k*' antibody, and that in the *Duffy* system as an 'anti-Fy^b' antibody, and consequently in these systems nowadays it is possible to genotype people. Similarly, in the *Rh* system, a large amount of genotyping can now be done.

Most blood groups are inherited independently of one another; but more recently it has been suggested that the *Lewis* group is linked with the *Lutheran* group[13].

Intensive studies have been carried out to try to associate blood groups with diseases. Iso-immunization of pregnancy is known to occur and may produce hæmolytic disease of the newborn. In these cases, the commonest responsible blood group is the *Rh* one. Linkage between blood groups and human characters has been studied many times, but no definite case of linkage has been established, although Penrose[14] has suggested a possible linkage between bright red hair and the *ABO* groups.

Blood groups are of especial interest in the study of human genetics because they are normal physiological characters, and as such are a feature of the whole population; moreover, from a genetical point of view, they are clear-cut characters, readily charted and scored; they are unaffected by environment. Their manner of inheritance is largely simple, the determinant genes being associated with one pair of chromosomes. They are, therefore, of great value in the study of human genetics, their wide distribution and complete penetrance always making them applicable, unlike other traits. It must be remembered, however, that the presence of the individual is required for such examination and studies; these therefore, are restricted to three or four generations and the possibility of illegitimacy must always be borne in mind. Nevertheless, the blood groups form a base-line from which to work, and it is desirable that human genetical studies should always be accompanied by a study of the blood groups, if this is possible.

Twinning is of considerable interest to human geneticists, and blood groups have been especially helpful in such cases. With the number of blood groups now known, if the twins are like-sexed, it is possible to calculate the chances of monozygosity[3]. The present writer has found it particularly useful in the study of a series of twins in which one child suffered from a congenital abnormality which the other did not possess; in a number of these cases the blood groups tended to show that the twins were monozygous.

Blood groups, of course, are of interest to the physician because of their importance in blood transfusion therapy, and they have also been used in cases of disputed parentage and in medico-legal work. In the case of disputed parentage, the *ABO*, *MN* and *Rh* groups are the ones that are used, because in these blood groups large numbers of family studies have been undertaken and their mode of inheritance is clearly defined and beyond doubt.

Landsteiner once said that blood groups would some day become as valuable as finger prints in the recognition of the individual. There is no doubt that recent studies have more and more established the individuality of the blood. There are now 300,000 blood-group combinations; some of these are extremely rare and occur very infrequently in the population. It is probable that more blood groups remain to be discovered; therefore, the study of human blood groups is one that assists in establishing the individuality of man, and the revised Medical Research Council publication is a valuable contribution on the subject.

ENERGETICS OF SENSORY EFFECTS

AT the recent meeting of the British Association in Belfast, Section I (Physiology) arranged a session entitled "Energy into Nerve Impulses". The first paper was by Prof. E. D. Adrian, president of the Royal Society, who spoke on the sense of smell. He said there is much evidence that the olfactory organ in man is far less sensitive than the larger organs in dogs or sharks and the much smaller organs in moths and insects. It is likely that this difference in sensitivity is due more to a greater power of discriminating scents than to a lower absolute threshold at the end organs. Prof. Adrian then turned to the results he has obtained by recording, with a fine electrode in the olfactory bulb, the nervous discharges which occur in the mitral cells of the rabbit, while the nose is subjected to a known concentration of a suitable substance. With most smells excitation is confined to each inspiration, and it is also found that the concentration which is just perceptible to the human nose differs very little from that just capable of producing an olfactory discharge in the rabbit. Nervous discharges recorded in this way show a number of features by which the discharge may be distinguished as due to a particular smell. The differences in the olfactory discharge are of two kinds, depending on differences in the excitability of the different receptors and of different regions of the organ to different materials; and on differences in the time course of the discharge, the latency, duration and rate of rise and fall in the frequency of the impulses.

Prof. Adrian first considered the different sensitivities of individual units. It is possible to distinguish one unit from its neighbours by careful placing of the electrode, and it is nearly always possible to find a substance which will excite this single unit at a concentration too low to excite the others. Thus, in one preparation the single unit responded to acetone in a concentration at which no other unit did, and to a concentration of amyl acetate which excited other units, while it was unaffected by pentane in a concentration that excited the others. The substances tested could be classed in two groups—water soluble and lipoid soluble. Units responding to one group rarely responded to the other, and there is also a regional distribution, the anterior parts of the organ responding mainly to the water-soluble group and the posterior part to the lipoid-soluble group. The latency of the response to the water-soluble group is always less than 0·025 sec., while with substances insoluble in water it is longer than 0·05 sec. The substances which excite after a short latency produce a short discharge, and vice versa. Prof. Adrian concluded by saying that some of these differences may depend on the gross structure of the organ, and he suggested that the specific sensitivities of the receptors might be related to the length of the terminal part of the cell, which varies. He thought it unlikely that olfactory discrimination depends on a limited number of distinct receptor types.

Dr. Hallowell Davis, director of research of the Central Institute for the Deaf, St. Louis, Mo., then discussed the problem of how mechanical energy is converted into nerve impulses in the inner ear. The sensitivity of the cochlea is so great that the movement of the basilar membrane at threshold is probably less than the diameter of a hydrogen atom, and the amount of energy is of the same order of magnitude as the energy of thermal agitation of the molecules. If the cochlea were a transducer, this energy would have to be converted extremely efficiently, and the nervous tissue involved would need to be on the verge of spontaneous discharge. Dr. Davis described the results of recent experiments and put forward a new hypothesis that explains the action of the cochlea as an electronic valve mechanism rather than a transducer. The cochlea microphonic has been suggested as the immediate stimulus to the terminals of the auditory nerve, but at one time it seemed difficult to reconcile this hypothesis with the long latency that had been observed between the peaks of the microphonic and the impulses. This difficulty no longer exists, however, because the summating potential which Davis and his collaborators previously believed to be a local potential in the receptor cells has now been shown by Davis and Tasaki to be an action potential in the nerve fibre in the neighbourhood of the hair cells. This shows that the latency in the initiation of the impulses is very short, and Dr. Davis stated that he now accepts the hypothesis that the cochlea microphonic is the immediate stimulus to the auditory nerve fibre.

There has been indirect evidence that the cochlea microphonic is associated with the hair cells of the organ of Corti, and very recent explorations of the cochlea, independently by Békésy at Harvard and by Tasaki at the Central Institute for the Deaf, have strongly supported this conclusion. The source (or sink) for the cochlea microphonics seems to be the hair-bearing end of the hair cells. This is where the hairs are embedded in the tectorial membrane, and Békésy has shown that it is radial movements of the tectorial membrane across the organ of Corti that are most effective in producing the cochlea microphonics. He has also shown that, if the tectorial membrane is displaced and held in its new position, the microphonic continues as a D.C. potential without further addition of mechanical energy. This provides direct evidence that the mechanism must be of an electronic valve and not of a transducer type. Békésy has found that the endolymph in the scala media is about 80 mV. positive to that in the other scalæ, and that the electrical resistance of the walls of the scala media is high. Dr. Davis put forward the hypothesis that the cochlea microphonic is due to changes in the current flowing from the scala media to the scala tympani, due to changes in the electrical resistance of the hair cells in the region of the hairs, and that this change of resistance is due to, and directly related to, the position of the hairs. He suggested that the source of energy that maintains the potential in the scala media may be in the stria vascularis.

The next paper was on "Light-Quanta into Nerve Impulses", and was given by Dr. M. H. Pirenne, of the Physiology Department, University of Aberdeen. Light falling into the eye causes nervous excitation in the retina and optic nerve, and it is generally accepted that a photochemical change in the retinal receptors is the first step in this process. The retinal receptors, the rods and cones, contain substances (such as visual purple in the rods) which absorb part of the incident light and undergo physicochemical changes in consequence. It is these changes that lead to nerve excitation. Light can only be absorbed in quanta, and fractions of quanta cannot be absorbed (the energy of a quantum is about 4×10^{-12} erg for $\lambda = 0 \cdot 51\,\mu$). Experimental measurement indicates that under the best conditions a rod can become excited when it has absorbed one quantum only. The light sensitivity of the rod, therefore, reaches the absolute physical limit. To enable a human subject to see a dim flash of light, however, a few neighbouring rods must be excited within a short time-interval. Thus, while a rod reacts to one quantum, the organism as a whole requires more than one quantum to give a visual response. One quantum is absorbed by one molecule and reacts with that molecule alone. There must therefore be some mechanism which can amplify such a one-molecule disturbance into a stimulus adequate to set up an impulse.

Dr. Pirenne then turned to the visibility of large, continuously exposed fields, a problem in which he has been interested recently. The threshold for such a field is of the order of 10^{-6} candle/sq. m. At threshold the retina receives extremely little light energy—on the average one quantum is absorbed every 0·1 sec. per 100,000 rods. One-tenth of a second is roughly the time during which the retina can summate the action of light. Physical fluctuations give some parts of the retina more, and others less, than this average, so there may be a group or groups of rods in the retina that are excited within the summation time. These figures show that, in order to make every rod absorb about ten quanta every tenth of a second, we must use intensities equal to about a million times the threshold intensity for a large field. If the central cones are as sensitive as rods, then the same will apply in the fovea, but, if the cones are less sensitive, then even more light will be required. Thus, a single cone cannot be activated with intensities below 0·1 or 0·01 candle/sq. m., simply because at such intensities they generally absorb no light at all. Thus, quantum phenomena probably play as important a part in cone as in rod vision. It can be shown, for example, that in the range from threshold to about 10^3 threshold intensity, the finest details just visible at each intensity are almost as fine as they could be. Visual acuity and retinal sensitivity in this range are linked together, almost reaching the limit set by the quantum properties of light.

In the last paper, on the "Initiation of Impulses at some Sensory Endings", Dr. J. A. B. Gray, of the National Institute for Medical Research, confined himself to considering mechanically stimulated receptors. Certain conditions must be fulfilled before an impulse is initiated at a sensory receptor. A certain minimum amount of energy must be provided; but, as most of this energy is absorbed by inexcitable structures, it is easier to talk in terms of compression or extension of the receptor. A Pacinian corpuscle which can be freed from its surrounding tissues can be excited by compression movements of less than $0 \cdot 5\,\mu$. With some receptors, including the Pacinian corpuscle, the stimulating movement must also have a minimum velocity, and in this receptor a threshold movement must be complete in about 1 msec.—that is, a velocity of about 0·5 mm./sec.

A minimum velocity is not a necessary condition of excitation for all receptors; Landgren has shown that some receptors in artery walls respond however slowly the pressure rises to its final value. Impulses can sometimes be excited as frequently as a thousand a second from Pacinian corpuscles. A stimulus which satisfies these minimal conditions excites an impulse after a short interval. In the Pacinian corpuscle this interval is about 1·5 msec. when the stimulus only just reaches threshold, but it is reduced to about 0·5 msec. if the stimulus is large. During this interval, the excitability of the ending is steadily increasing, a fact which is shown by giving a Pacinian corpuscle a mechanical stimulus too small to excite and testing its excitability with a short electrical pulse at intervals after the mechanical stimulus. The excitability increases up to the time at which a threshold mechanical stimulus would have initiated an impulse, and then declines. These excitability changes are probably caused by a local potential change that has been observed by Alvarez-Buylla and Ramirez de Arellano. This potential change, unlike the impulse, is confined to the ending, and its size is directly related to the size of the stimulus. Local potentials were first seen in sense endings by Katz, who recorded them from a stretch receptor from a muscle. The potentials from this receptor showed two components: an early peak the amplitude of which was related to the velocity of the stimulus, and a part which was related to the amplitude of the stretch and remained as long as the stretch was applied. This local potential is probably the immediate cause of the impulse. The mechanism by which the mechanical stimulus produces the local potential is not known, but it seems likely that the mechanical stimulus allows the electrical energy stored in the nerve cell to be released. Stretching a single node of Ranvier does not produce changes comparable to stimulating a sensory receptor. However, a suggestion that there may be specialization of the membrane of sensory terminals comes from evidence that acetylcholine may stimulate sense endings, though this substance seems to play no part in their normal function.

In the discussion that followed, Prof. Adrian was asked whether the adaptation to a smell that is commonly experienced is due to fatigue of the receptor. He replied that an impulse discharge can be recorded for long periods and that the adaptation is presumably central. Dr. Detlev W. Bronk referred to the importance of the chemical environment of nerves and the oscillatory phenomena seen with lack of calcium. Under these conditions impulses occur at intervals which are multiples of a fundamental interval; he said that Dr. Scott had observed similar rhythmical discharges from Pacinian corpuscles. Prof. W. Burns asked Dr. Davis whether the threshold of the auditory receptors could be altered by polarizing currents, to which the latter replied that they can be either raised or lowered according to the polarity of the current. J. A. B. GRAY

OBITUARIES

Dr. W. E. Gye, F.R.S.

W. E. GYE, internationally known as an exponent of the virus hypothesis of cancer, died in Perth, Western Australia, on October 13.

W. E. Bullock, who later changed his name to Gye, was born in the Derbyshire village of Beeston on August 11, 1884. The son of a railway signalman, he tried a number of occupations before becoming a 'pupil teacher'. Later, he obtained a scholarship tenable at University College, Nottingham, and gained the London B.Sc. in chemistry. After spending a year teaching in Birmingham, he began the study of medicine with the financial aid of a friend. During his student days Gye lived simply, found gainful employment during the vacations and repaid the assistance which he had insisted on regarding as a loan. He graduated in Edinburgh in 1913 (Gold Medal) and joined the staff of the Imperial Cancer Research Fund under Bashford and Murray. He served in the R.A.M.C. in charge of a field ambulance in France and Italy during the First World War, and on his return carried out investigations on anaerobic infections with W. Cramer.

Gye and Cramer studied the influences of chemical substances, calcium salts and silica, for example, in producing 'defence rupture' in wounds infected with spores of anaerobic bacteria. Shortly afterwards, Gye collaborated with E. H. Kettle in an investigation of silicosis and miner's phthisis. He then joined the staff of the National Institute for Medical Research with the intention of participating in the experimental studies of dog distemper which were then being planned. Before this work could proceed, a stock of virus-free dogs had to be bred and Gye, in order to obtain some virus experience, commenced work with the Rous sarcoma.

This work on fowl tumours was continued by Gye, and in 1925 he published a paper on the "Ætiology of Malignant New Growths" which attracted widespread attention. He attributed the specificity of various growths, not to a corresponding multiplicity of viruses but to 'specific factors' derived from the host. This thesis was further elaborated and presented together with many experimental observations on fowl tumours in a book with W. J. Purdy, "The Cause of Cancer", published in 1931.

Gye succeeded Murray as director of the Imperial Cancer Research Fund in 1936. The virus hypothesis continued to be one of his main interests, and the problem of obtaining direct and convincing experimental evidence of a causal virus in transplantable mammalian tumours occupied much of his attention. Because of his own negative results with tumour desiccates over a long period, it is perhaps not surprising that in 1949 he interpreted the successful transmission of such tumours in the Fund's laboratory by means of freeze-dried material as evidence of the existence of such a virus.

A gift of lucid exposition was one of Gye's characteristics. He undoubtedly rendered a great service to oncology by undertaking the study of the fowl tumours described by Rous before the First World War. These had been largely ignored because they could be induced *de novo* by virus obtained from them, and therefore could not be reconciled with other ideas on the genesis of cancer in general. Gye's attempts to extend the hypothesis of virus as a continuing cause to all kinds of cancer were highly ingenious, and it is largely due to him that this alternative to other concepts holds the position it does to-day. He believed fervently in his ideas, and in this controversial subject evoked reactions ranging from great admiration to pungent criticism.

Gye was a man of much personal charm. His post-war years were burdened by an increasing disability due to a heart condition, and on retirement from the directorship of the Imperial Cancer Research Fund in 1949 he went to Perth, Australia. He was elected a Fellow of the Royal Society in 1938 and in 1947 was appointed professor of experimental pathology in the Royal College of Surgeons. Gye was twice married, in 1913 to Miss Elsa Gye, who died in 1943 and by whom he had three sons; and in 1945 to Miss Ida Mann, professor of ophthalmology at Oxford. Miss Mann later retired and assisted Gye in his experimental work in London and in Australia.

J. CRAIGIE

Miss K. C. Boswell

MISS KATHARINE CUMMING BOSWELL, born in October 1889, died on September 19, of heat stroke, at Beni Abbes, deep in the Sahara. During her adult life she had a very close connexion with the (then) University College, Southampton. She was a student before and after the First World War; in 1926 she became a lecturer in the Department of Geography; she resigned her lectureship in 1944, and went as co-principal to the Friends' College, Jamaica, in 1945; she returned in 1949 and resumed close relations with the College and Department at Southampton.

Miss Boswell's main interest was in geomorphology, her studies in which were supported by her thorough learning in geography and by her early studies in geology and biology. Her constant aim was to understand, and to help others to do the same. Her students developed a lasting interest in their work and confidence that they could and should continue such studies long after they had left the University.

From the same desire to understand sprang her long and arduous struggle with the difficult "Morphologische Analyse" of Walther Penck. Controversy raged around his work. She determined that easy access to what he said was necessary. The last weeks, before she went to Algiers for the 19th International Congress of Geology, were spent in reading the proofs of her translation of Penck.

"Land forms under humid and under semi-arid conditions are well known, by personal experience, to the majority of geomorphologists. But I, for one, have never seen the real desert." She tried while visiting South Africa to see Namib but only penetrated the Kalahari. She died in the Sahara, victim of her desire to understand.

Miss Boswell was too modest ever to think that she might have any original contribution to make to geomorphology. Her friends knew otherwise. But understanding was all that K. C. B. asked, and died in pursuit of it.

F. C. Miller

NEWS and VIEWS

Royal Society : Awards of Medals

The following awards of medals have been made by the President and the Council of the Royal Society : *Copley Medal* to Prof. P. A. M. Dirac, for his remarkable contributions to relativistic dynamics of a particle in quantum mechanics ; *Rumford Medal* to Prof. F. Zernike for his outstanding work in the development of phase-contrast microscopy ; *Davy Medal* to Prof. Alexander Robertson for his researches into the chemistry of natural products, particularly the wide range of glycosides, bitter principles and colouring matters containing heterocyclic oxygen atoms ; *Darwin Medal* to Prof. J. B. S. Haldane for his initiation of the modern phase of study of the evolution of living populations ; *Buchanan Medal* to Sir Rickard Christophers, for his outstanding research on malaria and on the *Anopheles* mosquitoes which transmit that disease ; *Sylvester Medal* to Prof. A. S. Besicovitch, for his outstanding work on almost-periodic functions, the theory of measure and integration and many other topics of theory of functions ; *Hughes Medal* to Prof. P. I. Dee, for his distinguished studies on the disintegration of atomic nuclei, particularly those using the Wilson cloud-chamber technique.

Nobel Prize for Chemistry for 1952 : Dr. A. J. P. Martin, F.R.S., and Dr. R. L. M. Synge, F.R.S.

The Nobel Prize for Chemistry for 1952 has been awarded jointly to Dr. Archer John Porter Martin, head of the Physical Chemistry Division of the National Institute for Medical Research, Mill Hill, London, and Dr. Richard Laurence Millington Synge, biochemist at the Rowett Research Institute, Bucksburn, Aberdeenshire. Dr. Martin, after taking Part II of the Natural Sciences Tripos in biochemistry in Cambridge, worked at the Nutrition Laboratory there during 1934–38, mainly on vitamin E and nicotinic acid. Dr. Synge, who had also been trained at the School of Biochemistry, Cambridge, soon became interested, after a short spell in carbohydrate chemistry, in the analysis of proteins. The empirical methods then available for separating the complex mixtures of amino-acids present in protein hydrolysates were unsatisfactory in many respects, and Synge therefore investigated the possibility of separating the N-acetyl derivatives of amino-acids by partition between water and other solvents. In this early work, which was published in 1939, conventional extraction procedures were used. Realizing the relative inefficiency of these methods, Martin and Synge, who had now joined forces, designed and put into operation an all-glass apparatus based on counter-current principles. In 1938, both Martin and Synge accepted appointments at the Wool Industries Research Association laboratory in Leeds, and there ensued a close collaboration in which the respective capacities of these workers complemented one another in an ideal manner. It was realized that bulk extraction procedures were inferior to chromatographic techniques, and Martin and Synge conceived the idea that a combination of the principle of solvent partition and a chromatographic arrangement might be the solution to their problem. They soon found that a system consisting of water-saturated silica as stationary phase and a suitable organic solvent as mobile phase was satisfactory for their purpose. However, the acetylation step was somewhat cumbersome, and attempts were made to separate the amino-acids themselves. It was soon shown that cellulose was suitable as supporting material, and a logical extension of these findings led in 1944 to the development of the now generally familiar paper chromatography. A further and most important extension of these ideas led Martin (now at Mill Hill) to the development of liquid-gas partition chromatography.

Liquid–liquid chromatography, and especially paper chromatography, which were developed originally for the analysis of amino-acids, are now being used in almost every field of organic and inorganic chemistry and biochemistry. The application of these methods especially to the structure and metabolism of natural compounds has made possible advances in our knowledge which would have been considered impossible ten years ago. There has been during the past decade a widespread interest in the general problem of separation of small amounts of closely related substances, in no small measure due to the work of Martin and Synge. The development of synthetic ion-exchange resins, the various modifications of adsorption chromatography and the elaboration of bulk counter-current extraction methods have greatly increased our range of techniques. But the methods evolved by Martin and Synge are probably unique by virtue of simplicity and elegance of conception and execution, and also by the wide scope of their application. This field is still expanding, and it is likely that the invention of liquid–liquid chromatography will be considered by future generations as one of the more important milestones in the development of chemical sciences.

Dr. W. G. Penney, F.R.S.

The recent announcement, recorded in *Nature* of November 1, that Dr. W. G. Penney has been promoted to be knight commander of the Civil Division of the Order of the British Empire will be particularly welcomed by all associated with the Imperial College of Science and Technology. It was to this College of the University of London that Dr. Penney went in 1927, entering as a Royal Scholar. After gaining a first-class honours degree in mathematics he remained at the Imperial College for two more years, devoting his time to research work in mathematical physics. One result of this work was a paper written in collaboration with Dr. R. de L. Kronig which has become well known and is still widely read by students of metal physics. In 1931 he was awarded a Commonwealth Fellowship and continued his research work at the University of Wisconsin. Two years later he returned to Great Britain to study at Cambridge, where he became interested in the theory of molecular structures, a field of research in which he has made notable advances. In 1936 he was appointed reader in mathematics in the Imperial College and served in this capacity until the outbreak of the Second World War. Early in 1940, he undertook part-time research work for the Ministry of Home Security, and since that time has been increasingly concerned with defence research. The very important part which he has played in this field is now well known, and has been recognized, first, by the conferment of the O.B.E. in 1946, and now by the well-deserved honour recently announced.

Economies in the Department of Scientific and Industrial Research

In a written reply in the House of Commons on October 28 to a question from Sir William Wakefield regarding economies in scientific and industrial research (*Hansard*, col. 1735–7; October 28), the Parliamentary Secretary to the Ministry of Works, representing the Lord President of the Council, stated that no major plan or activity of the Department of Scientific and Industrial Research has been eliminated. A reduction of twenty-five posts in its non-industrial staff has brought the Department's establishment to 3,054. Planned recruitment has accordingly been halted, many outstanding vacancies cancelled and the reduced man-power resources re-allocated, reductions in headquarters staff and in the Building Research Establishment providing the further staff essential for the Mechanical Engineering Research and Hydraulics Research Establishments. The original estimates for the Department for 1952–53 have been reduced to £5,390,950 net, an increase of £24,950 over the estimates for the previous year, the total staff being now 4,049 as compared with 4,317 for 1951–52. Non-industrial staff currently authorized for the headquarters was 281 and for building research 420, as compared with 299 and 489, respectively, actually employed on October 1, 1951. In reply to the question whether the proposed cuts had been agreed by the Advisory Council for Scientific and Industrial Research, it was stated that the decision to restrict the available man-power and to reduce the estimates had been communicated to the Advisory Council and that the re-allocations were made with the Council's knowledge.

National Fuel Problems in Great Britain

The debate in the House of Commons on the Ridley report, recently initiated by the Ministry of Fuel and Power, afforded little evidence about a possible Government fuel policy. Reserve was to be expected in the adoption of some of the Ridley Committee's proposals, though the Minister in his rightly cautious remarks about co-ordination gave no suggestion that he has taken the hint given by the Committee and proposes to exercise the powers he already possesses in a way that would make the new body recommended in the report superfluous. Nor is the Minister prepared to recommend the provision of financial incentives to instal improved solid-fuel appliances for domestic heating, either to private consumers or to local authorities, even to the extent of removal of purchase tax. Equally he was unprepared to give industrialists any incentive to instal fuel-saving rather than other capital equipment. While accepting the Committee's view that competition should continue between the fuel and power industries and that, within a proper framework which maintains full freedom of choice for the consumer, the choice could be relied upon to bring about the best use of fuels, he ignored the essential condition laid down—that fuel prices should closely correspond to the relevant costs of supplying the different fuels. Apart from shirking this critical issue of price, neither the Minister nor his Parliamentary Secretary, who replied to the debate, succeeded in making it quite clear what was meant by their acceptance of the recommendation that an independent advisory service on fuel efficiency should be set up, controlled and financed by industry. The Ridley Committee recommended the continuance of the Ministry's own advisory service; but this the Minister proposes to cut down or at least limit to advice on fuel efficiency in government departments. The Parliamentary Secretary's efforts to elucidate this point are likely to have an unsettling effect on the technical advisers at present in the government service rather than to promote economy.

Scientific and Technical Information for Industry

In opening an industrial and commercial information exhibition at the Manchester Central Library on November 3, A. H. S. Hinchcliffe, after referring to his association with Sir John Stopford in forming the Manchester Joint Research Council in 1944, again stressed the importance of securing the effective utilization by British industry of existing knowledge, and the extent to which the Department of Scientific and Industrial Research is concerned with this problem as well as with the acquisition of new knowledge. Mr. C. Nowell, chief librarian of the Manchester Public Libraries, expressed the view that many of the smaller firms in the area are unaware of the existing facilities of the Commercial Library and Information Department, the Technical Library and the Reference Library in Manchester and the services they could render; Sir Raymond Street, in seconding the vote of thanks moved by Mr. Nowell, agreed that the small firm constitutes a major problem in raising the standard of efficiency and productivity in British industry. The exhibition, which has been arranged in association with the Department of Scientific and Industrial Research and the British Cotton Industry Research Association, illustrates not only the services and resources of the Manchester Public Libraries, and more particularly of the Technical Library and the Commercial and Information Department, but also the work of the Department of Scientific and Industrial Research. Although the main emphasis is laid on the work of the Department in disseminating scientific and technical information through its numerous publications and its own information department, some indication is given of the scientific and technical work carried out.

including, for example, a model of the calorimeter building at the Fuel Research Station and photographs illustrating the work of the Shirley Institute. The exhibition is admirably designed to achieve its purpose of demonstrating the value of technical information to industry in general.

Exhibition of Spanish Scientific Books

An exhibition of recent Spanish publications in science, technology and medicine, organized by the Institute of Spain, was opened by Mr. K. B. Potter, president of the Publishers' Association, in the Science Museum Library, on November 6. In welcoming the exhibition Dr. F. Sherwood Taylor, director of the Science Museum, recalled the evidence in Spain of the enormous antiquity of Spanish metallurgy and acclaimed the Spaniard as a great practical chemist and engineer. He looked back to the age of Alfonso the Wise, when Spanish astronomers led the world, to Ramon Lull, who founded a school important in the progress of chemistry, and to the debt owed to Spain for the development of the merino breed of sheep, founders of great flocks in three continents. This exhibition, he added, demonstrated the vigorous life of science in Spain to-day, particularly in the fields of medicine and engineering. His Excellency the Spanish Ambassador, in closing the ceremony, mentioned that the exhibition contains only a sample of the scientific books, particularly original treatises, published in Spain during the past few years—a period in which scientific activity has been intensified with the development of collective efforts in research and teaching as Spain has become increasingly industrialized. He also referred to the wide circulation of both standard textbooks and original works through Spain and Spanish America. In expressing his gratitude to the Science Museum for opening its library to the exhibition, he spoke of the universal interest in science, of the admiration in Spain for the scientific culture of Great Britain and of the world of science which speaks of friendship and a common task. The exhibition will remain open until November 20.

Quantitative Paper Chromatography of Plant Nitrogen

The value of quantitative partition chromatography on paper in the analysis of the alcohol-insoluble nitrogen of plants has been established in recent investigations by J. F. Thompson and F. C. Steward (*J. Exp. Bot.*, 3, No. 8, 170; 1952). The amino-acid composition of egg albumin, zein, edestin and cucumber seed globulin has been determined by a quantitative method which is described, the chromatographic analytical data accounting completely for the amino-acid nitrogen of the protein hydrolysate as determined by the Kjeldahl method. The analyses of the alcohol-soluble and -insoluble fractions of potato tubers of several varieties have now been carried out, attention being directed to differences which have been observed as between both samples and varieties. No correlation has been observed between the relative proportions of free amino-acids in the tubers and in the alcohol-insoluble protein; indeed, certain compounds present in the free state in the tissue do not occur in the protein, while the amides are stated to be considerably in excess of their possible occurrence combined in the protein. Hence the tentative conclusion is reached that the free soluble compounds are not directly combined as such to form proteins.

Petrological Identification of Stone Axes

The third report of the Committee concerned with the petrological identification of stone axes is published in the *Proceedings of the Prehistoric Society* for 1951 (Pt. 2). Polished celts are frequently made from fine-grained igneous rocks, tough materials making carpentry possible. In thin sections these rocks can be identified under a polariscope, and sometimes the material is not one of common occurrence. In such cases the site whence came the rock substance can be located, and indeed a number of such workshop sites are known. This third report continues the investigations and gives much more information on this interesting matter which helps to suggest the lines of ancient trade routes along which were passed the raw materials utilized for the making of ground and polished celts.

Reopening of the Mining Collection at the Science Museum, London

The Mining Collection at the Science Museum, South Kensington, London, S.W.7, will be reopened in much enlarged form by the Right Hon. Geoffrey Lloyd, Minister of Fuel and Power, on November 18. The basic conception in the design of the new Collection, which occupies an area of nine thousand square feet, has been to give the visitor the impression of being underground in the actual workings of a mine; one of the principal exhibits is a full-scale model of a coal face supplied with the latest equipment and machinery. Adjacent to this are various sections illustrating the historical development of the many ancillary services which are essential in mining and which have played such an important part in the safety and social progress of the miner; these sections deal with coal-cutting, metalliferrous mining, breaking ground, mine transport, winding, boring and sinking, mine lighting, mine ventilation, rescue work, hand tools, roof supports and surface mining. The development and building of this Collection has only been made possible by the kindness and generosity of the many manufacturers of mining equipment used in Great Britain, who have provided not only full-sized equipment but also many fine models and finance.

Insignia Award of the City and Guilds of London Institute

The City and Guilds of London Institute has recently established an "Insignia Award" in technology which is designed to be a mark of distinction conferred by the Institute on those who have combined with a sound practical training an adequate knowledge of the fundamental scientific principles of their industry and have shown a capacity for leadership and administration and for applying such wider knowledge to their particular industry. The Award will entitle the holder to use the letters C.G.I.A. after his name. The five main sections at present approved for the Award are the chemical, constructional, electrical, mechanical and textile industries; but these divisions are meant to cover a broad range of particular industries. The preliminary conditions required of a candidate are that he be not less than thirty years of age, have completed the full period of apprenticeship or equivalent training suitable for his industry, have obtained the Full Technological Certificate of the Institute in an appropriate branch of technology, have had at least seven years suitable industrial experience subsequent to his initial apprenticeship (except in very special circumstances, war service cannot be taken into account), and give the names of three referees. The two main tests for the Award are the writing of a thesis and the subsequent interview by a body of experts. As regards the former, the candidate is not expected to present a record of original research, but rather give a critical appreciation of a problem in industry, backed by relevant reading, with practical suggestions for solving the problem and for future developments ; it is suggested that ten to twenty thousand words should be the length of the thesis. The interview, to which much importance will be attached, is designed to gain an appraisal of the candidate's education, training and career, together with any possible points arising from his thesis. All communications regarding the Award should be addressed to the Director, Department of Technology (I.A.), City and Guilds of London Institute, 31 Brechin Place, South Kensington, London, S.W.7.

Mineralogical Society : Officers 1952-53

THE officers of the Mineralogical Society for 1952–53 have been elected as follows : *President*, Dr. J. Phemister ; *Vice-Presidents*, Dr. A. F. Hallimond and S. J. Shand ; *Treasurer*, Prof. J. H. Taylor ; *General Secretary*, Dr. G. F. Claringbull (c/o Geological Society, Burlington House, London, W.1) ; *Foreign Secretary*, Dr. L. J. Spencer ; *Editor of the Journal*, Dr. L. J. Spencer.

University of London : Appointments

THE following appointments have recently been made in the Imperial College of Science and Technology, London : Dr. E. A. R. Braude, to the University readership in organic chemistry ; Mr. M. W. Humphrey Davies, to the University readership in electrical engineering.

Christmas Lectures in London for Juveniles

LECTURES for juvenile audiences in London during the forthcoming Christmas holidays have been arranged as follows. At the Royal Institution (21 Albemarle Street, London, W.1) the 123rd course of lectures will be given on December 27 and 30, 1952, and January 1, 3, 6 and 8, 1953, by Dr. F. Sherwood Taylor, director of the Science Museum, his subject being "How Science has Grown" ; the fee for these lectures is children (10–17 years) £1, adults £2. At the Royal Photographic Society (16 Princes Gate, London, S.W.7) three lectures on "How We see Colour", "How We Measure Light" and "Putting Colour into a Photograph" will be given on January 1, 2 and 5, 1953, respectively ; tickets can be obtained, without charge, from the Secretary of the Society.

Announcements

H.R.H. THE DUKE OF EDINBURGH has been elected president of the Royal Society of Arts. Her Majesty the Queen, who, as Princess Elizabeth has been president since 1947, now becomes patron.

THE Lord President of the Council has appointed Sir Hugh Beaver, managing director of Arthur Guinness, Son and Co., Ltd., to be a member of the Advisory Council for Scientific and Industrial Research. Mr. I. A. R. Stedeford, chairman of Tube Investments, Ltd., has resigned his membership of the Council because of pressure of other duties.

PROF. A. J. KLUYVER, president of the Royal Netherlands Academy, will deliver the Leeuwenhoek Lecture at the Royal Society on November 20 at 4.30 p.m. The subject of the Lecture will be "The Changing Appraisal of the Microbe". Applications for invitations should be sent to the Assistant Secretary, Royal Society, Burlington House, London, W.1.

THE Anglo-Saxon Petroleum Co., Ltd., has informed University College, London, that it intends to give the College £2,700 annually for the provision of scholarships in chemical engineering and of apparatus for the furtherance of the study of chemical engineering in the Ramsay Memorial Laboratory.

THE Humber Laboratory, at Wassand Street, Hull, a new out-station of the Torry Research Station, Aberdeen, will be opened on December 5 by Sir Ben Lockspeiser, secretary of the Department of Scientific and Industrial Research, supported by Admiral Sir Robert Burnett, chairman of the White Fish Authority, and Mr. J. Croft Baker, chairman of the British Trawlers' Federation. Dr. C. L. Cutting is in charge of the new Laboratory.

AN appeal has been put forward by Mr. James Paton (*Irish Astro. J.*, **2**, No. 2 ; June 1952) for aurora observers to co-operate in the proposed survey of the frequency of auroræ over the British Isles. The primary purpose of the work is to prepare a map of the area covered by the survey, showing the frequency of aurora nights in each latitude. The success of the scheme requires a large number of observers, and those who are willing to co-operate or who require further information should write to Mr. Paton at the Department of Natural Philosophy, University, Drummond Street, Edinburgh, 8.

THE Institute of Rural Life at Home and Overseas, in co-operation with the Association of Agriculture and the Institute of Education, University of London, is arranging a meeting on "Food Science at Home and Overseas", to be held in two parts, on the mornings of November 22 and 29 respectively, at the Institute of Education, Malet Street, London, W.C.1. The meeting, for which a fee of 1*s*. (including coffee) is charged, is designed primarily for school teachers and students and will consist of four lectures by well-known authorities. Application forms and further information can be obtained from the Secretary, Institute of Rural Life, 84 Eccleston Square, London, S.W.1.

A series of four public lectures has been arranged by the School of Pharmacy, University of London, to commemorate the granting of a Royal Charter to the School. They are : "Organic Chemistry at the Cross-Roads", by Prof. J. W. Cook, regius professor of chemistry in the University of Glasgow (November 18) ; "Adsorption and Reaction in Monolayers and some Biological Implications", by Sir Eric Rideal, professor of physical chemistry, King's College, London (December 2) ; "Genetics and Medicine", by Dr. C. D. Darlington, director of the John Innes Horticultural Institution (December 15) ; "The Future of Pharmacy and Pharmacology", by Sir Henry Dale (February 18). The first two lectures will be delivered at the Westminster Medical School, Horseferry Road, London, S.W.1, and the remaining two at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1 ; the lecture hour is 5.30.

BREWING INDUSTRY RESEARCH FOUNDATION

NUTFIELD, SURREY

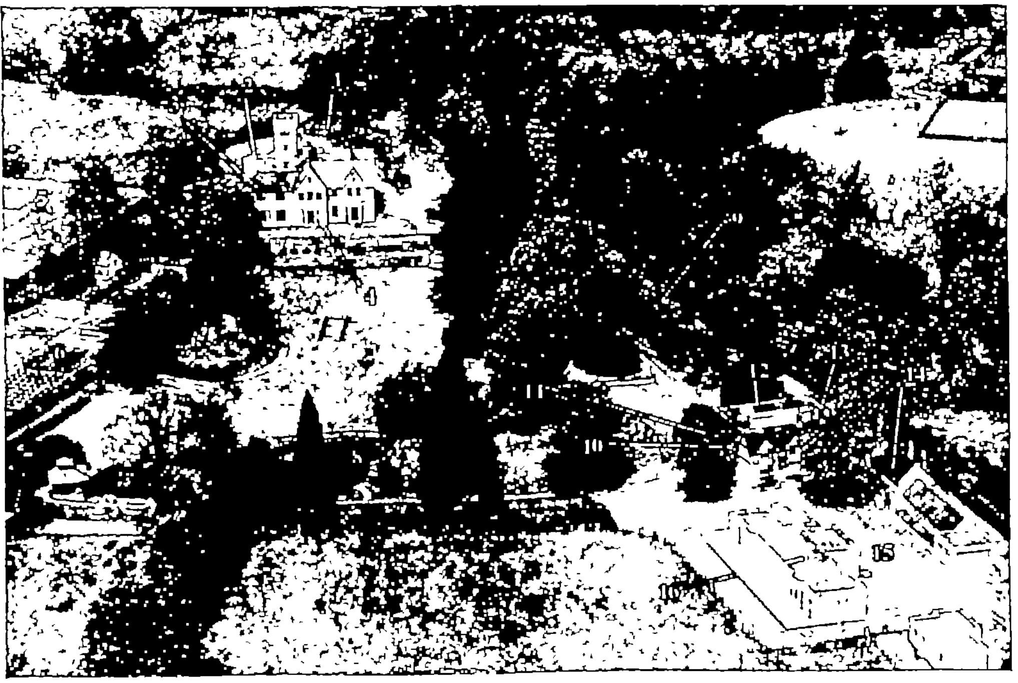
THE new Brewing Industry Research Foundation at Lyttel Hall, Nutfield, Surrey, marks the fulfilment of a scheme developed over many years by the Institute of Brewing and made possible by the generosity of the Brewers' Society. It has been specifically designed for the scientific study of brewing and fermentation generally, with particular emphasis on the fundamental aspects of the many problems involved. Lyttel Hall itself has been skilfully modified and adapted to provide an extensive range of laboratories and other facilities in attractive surroundings. With its staff of scientific specialists and technicians under the direction of Sir Ian Heilbron, the Foundation occupies a unique place among industrial research institutes.

Not unexpectedly, versatile experimental breweries provide a focal point in the Foundation. Of these the larger, of ten gallons capacity and constructed of stainless steel, is complete with air-conditioned fermentation and beer-storage rooms, bottling plant, and pasteurizing equipment.

These breweries form part of an Applied Research Division designed to study, in the light of existing knowledge, the materials and processes of brewing as used to-day, but in greater depth and with greater accuracy than is possible in a commercial production plant. Further, this Division will assist the industry by formulating new or improved methods of analysis and also engage in general technological investigations covering all aspects of brewing.

Another important function of this Division is the much-needed examination of new varieties of barleys and hops for the National Institute of Agricultural Botany, Cambridge, and the hop research stations at Wye College and East Malling, Kent, as a preliminary measure of their brewing value. These tests include brewing trials of the more promising samples, and are of great value to the plant-breeder as they permit comparative tests to be made on small quantities of materials, thus saving valuable time and acreage.

The empiricism which for long characterized the traditional industries—and is, it must be borne in mind, still dominant in brewing—must inevitably be succeeded by scientific knowledge if full economy in the use of raw materials and complete control of operations is to be achieved. With this background, a wide range of studies is in progress in the other two main divisions of the Foundation. Of these, that devoted to microbiology forms a self-contained unit of three laboratories with a complete range of ancillary service rooms in which the most exacting studies of yeast and brewing bacteria can be carried out. The problems here are formidable, and of necessity begin with a survey of the almost unexplored field of British primary yeasts, a survey rendered peculiarly arduous by the difficulty of adequately characterizing and differentiating such yeasts. Similar difficulties complicate the complementary study of 'wild' yeasts—those adventitious



Brewing Industry Research Foundation, Lyttel Hall. 1, Lodge; 2, model brewery; 3, administration offices; 4, main experimental block; 5 and 6, kitchen gardens; 7, swimming pool, 8, ornamental lake; 9, Cooper's Hill Road; 10, electrophoresis laboratory; 11, ultracentrifuge laboratory; 12, light-scattering laboratory; 13, mechanics' workshop; 14, residential cottages; 15, ancillary workshops, 16, canteen

contaminants which often have a deleterious effect on the beer. Again, beers are commonly susceptible to attack by certain types of bacteria, and although our knowledge here is more extensive than with the 'wild' yeasts, there is still need for further systematic study.

In this connexion the preservative action of hop resins assumes outstanding importance. Renewed attention is being given to means of estimating this effect by appropriate microbiological assay, a problem of peculiar difficulty because of the desirability that any test should reflect actual brewing conditions. The microbiological laboratories are also engaged on miscellaneous research such as the systematic examinations of the potential effects of selective herbicides and other agricultural chemicals on the malting quality of barley. Attention is also being directed to genetic studies on yeast, and to the possibilities of yeast hybridization. While many of these topics are of outstanding scientific interest, it must be emphasized that considerable research effort must perforce be devoted to essential but comparatively unspectacular groundwork. The need for this acutely reflects the sparse attention which has hitherto been paid to the scientific study of industrial microbiology, especially in Great Britain. For this reason an institute in which this largely neglected field receives prominence assumes special significance in view of the present meagre university facilities available for such studies.

Finally, mention should be made of the fact that in 1951 the Foundation undertook the important responsibility of maintaining the National Yeast Culture Collection. Some two hundred organisms were originally inherited from the National Collection of Type Cultures, and a further hundred and sixty yeasts of special interest have since been added. Work on the re-authentication of the cultures is already in progress, one-third of the total having been checked. Over the past year, nearly two hundred requests for yeasts have been received both from Britain and from abroad, and it is expected that this figure will increase as more yeasts are added to the Collection and its uses become more widely recognized. It will be appreciated that the National Yeast Culture Collection provides a service which extends far beyond the limits of the brewing industry.

The Chemical Division, which constitutes the third main section, comprises an extensive range of laboratories in which liberal facilities are provided for detailed research in the field of the industry's operations. Much thought has been given to the equipment of these laboratories, in which are installed all the apparatus, instruments and plant necessary to keep abreast of modern advances and techniques throughout the world. For example, the physical-chemical laboratories include the latest type of air-driven ultracentrifuge, electrophoresis apparatus and light-scattering equipment, all indispensable for immediate and long-term research.

The research programme covers the chemistry and biochemistry of the raw materials used in brewing and of the changes which they undergo during the various stages of the brewing process. Of these malt is pre-eminent, providing as it does the substance of beer, while hops supply the flavouring and preservative principles. An important early stage in malting consists of steeping the stored barley in water, an operation which it is now recognized results not merely in the uptake of water, but also in the simultaneous removal of a miscellany of substances. Among the latter are compounds which prevent or retard the normal germination of the grain. The isolation and study of these inhibitors are of considerable importance, for their planned use may conceivably lead to a higher degree of control of malting than has hitherto been possible; this aspect is now being investigated by means of specially designed experimental maltings. The barley grain is primarily a store-house for starches and proteins which are ultimately converted by specific enzymes into simpler compounds, such as dextrins and sugars on one hand and peptides and amino-acids on the other. A considerable effort is being devoted to the detailed study of these materials in barley, malt and wort, as well as to other constituents of the raw materials, notably pectins and tannins. Attention is also being given to the major constituents of hops, more particularly the resins: although the importance of these has been appreciated for years, their full significance has still to be elucidated. This is evident as a result of the application of new techniques to their examination, whereby unsuspected constituents have been revealed.

In addition to these specific studies, many other brewing problems will ultimately only be interpreted as a result of fundamental scientific research. The formation of a 'head' on beer is thought to be associated with the presence of residual proteins; but their identification is still lacking and, moreover, there is complete ignorance of the physics and physical chemistry underlying the phenomenon. Again, the deposition of part of the residual proteins after processing frequently gives rise to the formation of an undesirable haze in the finished beer, and this is being given precise study in the hope ultimately of limiting the incidence of the responsible proteins.

In addition to its laboratory facilities, the Foundation houses the largest specialized brewing library in Great Britain. As part of its functions, it prints and distributes monthly to brewers throughout the country a bulletin of current literature which surveys, without abstracting, all incoming journals, thereby giving the brewing scientist notice of an article within four to six weeks of publication. The library also supplies on request photo-copies of scientific literature, a service which fills a long-felt want and is much appreciated.

This brief survey will serve to demonstrate that the Brewing Industry Research Foundation has not been set up solely to serve the immediate needs of an industry in respect of routine control and *ad hoc* problems, but equally for the prosecution of basic research, without which a full understanding of the vital processes involved can never be attained. The Director, appreciating the breadth of the field which must be covered and the many kinds of scientific experience required for such a task, has wisely taken steps to foster contacts with many university departments and, as occasion demands, to initiate therein extra-mural work.

The visitor to Lyttel Hall is left with a deep impression of an organization which, in its conception and in its whole scientific outlook, is destined not only to contribute substantially to industrial progress, but also, by its own contributions to fundamental knowledge, to take its place as a research centre worthy of the best traditions of Great Britain.

ROYAL SOCIETY OF CANADA

MEETING AT LAVAL UNIVERSITY, QUEBEC

THE Royal Society of Canada held its annual meeting at Laval University, Quebec, during June 2–4. In Section III (Chemical, Mathematical and Physical Sciences) of the Society, the following new Fellows were elected: P. E. Gishler, L. Katz, W. B. Lewis, D. W. R. McKinley, P. Scherk and H. L. Welsh. Dr. G. Herzberg gave his presidential address on "Forbidden Transitions in Diatomic Molecules". This was one of three interesting papers in a symposium on forbidden transitions. The others were "Forbidden Transitions in Atoms", by A. G. Shenstone, and "Forbidden Transitions in Nuclei", by L. G. Elliott.

About a hundred papers were presented before the sub-sections—chemistry, mathematics, astrophysics and spectroscopy, nuclear physics, meteorology and other branches of physics.

Chemistry. The programme of the chemistry sub-section consisted of a series of papers in organic chemistry (P. E. Gagnon *et al.*) and several in physical chemistry. The photolysis of azomethane has been investigated over the temperature-range 25°–190° C. (M. H. Jones and E. W. R. Steacie). Experiments on the photolysis of deuterated methylamines have shown that both the C—H and N—H bonds are ruptured (J. S. Watson and B. deB. Darwent). Various forms of deuterated pentanone-3 have been synthesized (L. C. Leitch and A. T. Morse). The assignments of certain infra-red absorption bands between 1,350 and 1,475 cm.$^{-1}$ to the bending vibrations of the C—H bonds of methyl and methylene groups located at specific positions in the molecule have been confirmed in forms of deuterated pentanone-3 (B. Nolin).

Mathematics. Three papers were presented in algebra and number theory, eight in analysis, and two in geometry. The significance of the work presented and the general interest and enthusiasm made this meeting the most outstanding of any yet held by the mathematics sub-section. It was generally agreed that the upsurge of activity on the part of Canadian mathematicians is due to the stimulus of the biennial seminars of the Canadian Mathematical Congress and especially to the influence of the Summer Research Institute.

Astrophysics and Spectroscopy. The astronomical papers included a discussion of the determination of the masses of eclipsing binaries, the study of interstellar matter, the investigation of the line profiles of *Be*-type stars, and the development of new techniques for the determination of time. The orbital elements of the exceptionally massive eclipsing system, H.D. 228854, have been deduced (J. A. Pearce). These stars are of special class *O* 7 with temperatures of 33,000° K. The orbital inclination is nearly 90°, and the relative orbital velocities are exceptionally large (710 km./sec.). The combined mass is seventy times the sun. A new catalogue of 1,346 variable stars in globular clusters has been prepared (Helen S. Hogg). Investigation of the absorption lines of the eclipsing stars Zeta Aurigæ when light of the hot star traverses the atmosphere of the larger and cooler companion has provided evidence of major prominence activity of irregular character (A. McKellar and R. M. Petrie). The intensities of interstellar sodium and calcium lines for 142 early-type stars have been used to derive a relation between distance and intensity (C. S. Beals).

Relatively high-dispersion spectra of the aurora have been obtained in the region 3300–8900 A. (W. Petrie). The near-ultra-violet emission bands of the N_2^+ molecule support the value 9·75 eV. for the dissociation energy (A. E. Douglas). The rates of change of polarizability with respect to internuclear distance have been found from the ratio of the intensities of Raman and Rayleigh scattering in gases (E. J. Stansbury, H. L. Welsh and M. F. Crawford). Experimental and theoretical results on the splitting of nuclear magnetic resonance absorption lines in single crystals by the interaction of the nuclear electric quadrupole moment with the electric field gradient within the crystal were reported (G. M. Volkoff).

Nuclear Physics. A heavy and varied programme of nuclear physics papers on heavy cosmic primaries in photographic emulsions, photonuclear reactions, neutron physics, radioactive nuclides, and mass spectrometry was presented.

Several papers on neutron physics from the Chalk River Laboratory will be briefly reviewed. Work on the resonant scattering of slow neutrons by samarium, gadolinium, europium, dysprosium and cadmium was reported. The scattering and total cross-sections of cadmium in the resonance region accurately obey the Breit–Wigner one-level formulæ. The total cross-section at resonance is 7,900 barns (B. N. Brockhouse). The neutron capture γ-ray spectra from the even-charge nuclei titanium, chromium, iron, nickel and zinc, and from the odd-charge nuclei scandium manganese, cobalt and copper, were shown and discussed in terms of nuclear shell theory (B. B Kinsey and G. A. Bartholomew). The angular distributions of prompt fission neutrons with respect to the direction of motion of the light and heavy fragments from the thermal neutron fission of uranium-233, -235 and plutonium-239 show that the neutron emission probability is 30 per cent greater for the light fragment (J. S. Fraser and J. C. D. Milton) The neutron capture cross-section for $^{59}\mathrm{Co}(n,\gamma$ $^{60m}\mathrm{Co}$ (10·7 min.) was reported as 19 barns (N. Mos and L. Yaffe). The nuclide radium-227, produced by the $^{226}\mathrm{Ra}(n,\gamma)^{227}\mathrm{Ra}$ reaction with a cross-section o 22 barns, is a β-emitter with a half-life of 41·2 min. a maximum energy of 1·30 MeV., and γ-rays o approximately 291 and 497 keV. (J. P. Butler and J. S. Adam). A curious time behaviour of positon annihilated in liquids and solids was reported. I metals and several other materials, positons ar annihilated with a single mean life-time of abou 2×10^{-10} sec. In other materials (for example, water ice) two distinct life-times were observed—abou 3×10^{-10} sec. and 2×10^{-9} sec. (R. E. Bell and R. L. Graham).

Papers on the radioactive properties of neutron deficient nuclides, cadmium-105 and -104, silver-104 xenon-123, -122 and -121, produced by proton bombardment in the McGill University cyclotron, wer read (J. S. Foster, F. A. Johnson and D. E. Tilley) The X-rays from the 70-MeV. synchrotron at Queen' University have been used to study depth–dos relations in a 'Plexiglas' phantom, the absorption c 17·5-MeV. X-rays in various absorbers with the a of $^{63}\mathrm{Cu}(\gamma,n)^{62}\mathrm{Cu}$ as detector, and the production an cross-sections of photonuclear reactions such as the (γ,n) reactions in carbon-12, copper-63, silver-107 and molybdenum-92 and the reactions $^{12}C(\gamma,3\alpha)$ and $^{16}O(\gamma,4\alpha)$ (J. A. Gray *et al.*). The 25-MeV. betatron at the University of Saskatchewan can be held constant to 5 keV. at a pre-selected energy. Photo-activation curves have been obtained which show a fine-structure that is attributed to absorption by individual levels in the reacting nucleus. The ratios of the cross-sections for the (γ,n) reactions leading to the ground and isomeric states in bromine-80 and molybdenum-91 have been measured and related to the spins of the reacting particles (L. Katz, R. N. H. Haslam *et al.*). Excellent agreement with experimental results on the capture of electrons by protons in hydrogen is obtained if both the ion – nucleus interaction and the electron – ion interaction are included as perturbations in a calculation using the Born approximation (J. D. Jackson and H. Schiff).

Other Branches of Physics. Papers in meteorology included a discussion of the conditions for the production of low-temperature fog (W. L. Godson), a correlation between types of snow crystal and the temperature at the height of formation (L. W. Gold and B. A. Power), and evaluation of fluctuating radar weather echoes (J. S. Marshall and W. Hitschfeld). A method for measuring sub-surface velocities in the Gulf Stream was described (E. E. Watson). A flow-meter, utilizing the cooling of a thermistor element, has been found suitable for measurement of small velocities in liquids (A. D. Misener).

A number of papers were presented on the properties of dielectrics, theory of diffraction, sources of sound, vibration of plates, infra-red detection, and an absolute measurement of the ohm. The failure of the Clausius–Mosotti equation for certain artificial dielectrics was explained in terms of the random distribution and shape of the metallic particles (H. E. J. Neugebauer). Discrepancies between diffraction theories and measurements close to a circular aperture under the influence of a plane acoustic wave have been traced to rapid oscillations in field intensity within the aperture (G. Bekefi). An improved method of calculating the diffraction of electro-magnetic waves by small apertures and scattering by small conducting bodies was reported (A. F. Stevenson). Calculations and observations have been made on the vibration patterns of thick barium titanate disks (R. R. Aggarwal and E. A. G. Shaw). The usefulness of physical theory in solving engineering problems was well demonstrated in a study of chopper-type sources of sound for fog-horns and air-raid sirens (G. J. Thiessen).

Three papers on low-temperature and solid-state physics were read (D. K. C. MacDonald). By suitably modifying a Collins helium liquefier, continuous measurements of electrical resistances of metals over a wide range of temperature have been made. The variation of characteristic temperature has been examined and carefully compared with the corresponding calorimetric data. The problems of anharmonicity in lattice vibrations and of melting are of particular interest, together with the adequacy or otherwise of the Debye model. The anomalous minimum of electrical resistance found at about 10° K. in copper has been systematically investigated with specimens containing controlled small percentages of tin, silver, nickel, lead, bismuth and carbon. Scattering cross-sections can be deduced from the residual resistances. B. W. SARGENT

EMPLOYMENT PROBLEMS OF DISABLED YOUTH IN GLASGOW

INCREASING concern about the employment of the disabled led, in 1944, to the passing of the Disabled Persons (Employment) Act. It was provided in the Act that the Ministry of Labour should establish and maintain a voluntary register of disabled people and that the larger firms should be obliged to employ a quota of workers who were registered in this way. The Act also gave the Ministry power to set up units to train or rehabilitate the disabled.

The practical application of these measures brought many difficulties to light and made it clear that much more detailed information was needed about the medical problems of placing disabled people in employment. In 1948, therefore, the Ministry of Labour asked the Medical Research Council to help. The Council's Occupational Medicine Committee agreed that the first necessity was to collect information about the incidence of disability and the extent to which the various forms of disability interfered with employment, and on its recommendation the Council set up a special Committee on the Resettlement of the Disabled.

A memorandum has now been prepared recording an investigation which was carried out under the ægis of this Committee into the employment experience of two groups of young people in Glasgow; one, a group of registered disabled, the other made up of children who had been to special schools for the physically handicapped*.

In the first group, 683 young persons were registered as disabled and, of these, 104 were not covered by the investigation for various reasons. Of the remaining 579, 146 had infective and parasitic diseases and 164 had diseases of the nervous system. About 18 per cent of the group were found to be unemployed and, of those in work, the majority were employed as semi-skilled manual workers, although quite a number were employed as skilled workers in crafts like boot repairing, cabinet making, market gardening, painting, watch repairing, upholstering, glazing, sheet metal work, baking and bookbinding. Unemployment was noticeably high among the group disabled by diseases of the nervous system; this group included epileptics and congenital paraplegics. The groups disabled by tuberculosis and mental defect showed degrees of unemployment that were substantially above the average. The groups disabled by malformations, poliomyelitis, diseases of the ear and of bones all showed low unemployment-rates. Many of the young people disabled by congenital malformations, accidents, circulatory diseases and poliomyelitis were engaged in non-manual work, while a relatively high proportion of those disabled by poliomyelitis and deafness secured skilled manual work.

The general employment picture was most favourable among those disabled by poliomyelitis and deafness. In the former group this is probably because the disability is not progressive, seldom affects more than one member of the family, and does not often involve the loss of many years schooling. There is a belief that the character of the poliomyelitic patient tends to be robust and free from self-pity. In this survey the way in which they regarded their disability was outstandingly healthy and free from emotion; many drove themselves hard in their efforts to achieve independence.

---

* Employment Problems of Disabled Youth in Glasgow. (London H.M.S.O.) 3s.

Another, and in many ways complementary, aspect of the employment problem for disabled youth concerns the number of jobs which a boy has held since registration; thus the high unemployment-rate of the seventy-two who were disabled by conditions affecting the nervous system was accompanied by frequent changes of job. Those disabled by bone diseases also had a high rate of job turnover; but they did not have so much long-continued unemployment.

The most stubborn resettlement problem in the whole survey centred around the seventy-two young people who were disabled by conditions affecting the nervous system. Twenty-six of them were epileptics and forty-two have been paralysed since birth, with disabilities ranging from the involvement of one limb to hemiplegia and diplegia with athetosis. The epileptics showed a fairly uniform picture of unemployment unless medical treatment could control their fits. "Until that happens the epileptic often lives the life of an outcast and is likely to become intensely frustrated and the despair of his family." The only other group approaching the bad employment record of the "nervous system" group was that of the forty-eight mentally handicapped children, of whom forty-three had been educated at special schools for the educationally retarded. The parents of these young people agreed that work of some sort was of great value and that a few weeks of idleness after leaving the discipline of school might be fatal to the future of the youth and render him unemployable.

The most searching criticism of the Disabled Persons (Employment) Act concerned the difficulty, or even the impossibility, of obtaining training courses which were still advertised. The Ministry of Labour and National Service arranged training for twenty-four (4 per cent) of the disabled young people and in ten cases it was given at a Government training centre. In three cases training was given in private or local education authority commercial colleges: two took a general commercial course and one shorthand and typing. The remaining eleven were trained under a scheme of grant by employers approved by the Ministry. At the time of the survey, only 153 youths of the group of 579 were serving an apprenticeship or undergoing a period of training.

The unemployment-rate of these trainees was low and their job stability high, for, at the time of the survey, thirty of the 115 were still holding the same job as they had had when they registered; the great majority of the others had not been employed at the time of registration.

During the survey the young people were asked if they had been given any special advice when they left school regarding suitable employment. The great majority answered "no", though they occasionally recollected that "a teacher had complimented them on their schoolwork and suggested that they should take up art or the like".

Of the social factors affecting the employment of these disabled young people, inadequate housing was found to be of the greatest significance; 113 of the disabled young people included in the survey were existing under conditions that could only be described as appalling. It was also shown that, where there was a high incidence of paternal unemployment, unemployment was prevalent among the children also.

In the second survey, inquiries were made into the employment experience of 408 young people who had previously left schools for physically handicapped children; the findings of the observers were generally similar to those in the first series of the investigations, despite the fact that only 30 per cent in the section group were officially registered as disabled.

The bulletin also contains an account of the work of the Danish Invalidity Court. During the years 1938–44 some 10,000 notifications of "invalidity" were received by the Court, and during the same years 3,167 disabled Danes received "vocational measures" under the auspices of the Court: 1,296 of these had started training before the age of eighteen. From this and other data it would appear that the proportion of disabled young people who receive vocational training is considerably higher in Denmark than in Great Britain.

The general conclusion of the Medical Research Council's Occupational Medicine Committee is that "it is impossible to view with other than apprehension the circumstances disclosed by this study of the welfare of disabled young people. The extent of unemployment and, perhaps more important, the extent of long-term chronic unemployment, and the high proportion of the employed who are engaged in unskilled work which is often grossly unsuitable and likely to lead to physical breakdown or prolonged idleness—these are sinister findings, especially when viewed against the general background of full employment in the past few years. Failure to settle young people of this age group in suitable work must inevitably make a major contribution to the vicious, hard core of unemployment in later years".

Apart from the overriding need to improve basic living conditions, particularly housing, and to harness all the resources of medicine for the prevention of disease, the Committee makes four suggestions which would help to settle disabled young people satisfactorily in employment. It recommends mitigation of the gross educational lack that adds to the difficulties of so many of these young disabled people; adoption of energetic steps to secure satisfactory settlement before the young person begins to drift; the provision of adequate and suitable training courses for disabled young people; and intensive medical and surgical treatment where necessary and the provision of any necessary medical aids or surgical appliances.

ENZYMIC DEGRADATION OF PECTIC ACID AND THE COMPLEX NATURE OF POLYGALACTURONASE

By AUDREY AYRES, J. DINGLE, A. PHIPPS, W. W. REID and G. L. SOLOMONS

Research Department, H. W. Carter and Co., Ltd., Coleford, Glos.

THE pectic enzymes produced by *Aspergillus fœtidus*, Thom and Raper, when the organism is grown on solid bran media [(*S*) type], are different from those produced by growth in submerged culture in liquid media [(*D*) type]. The (*D*) preparations have an optimum *p*H of 5·3 on sodium pectate as substrate, the (*S*) type 4·5. Both types of enzyme reduce the viscosity of pectic acid, until no precipitate is given either with ethanol or calcium ions, and reducing groups are formed simultaneously.

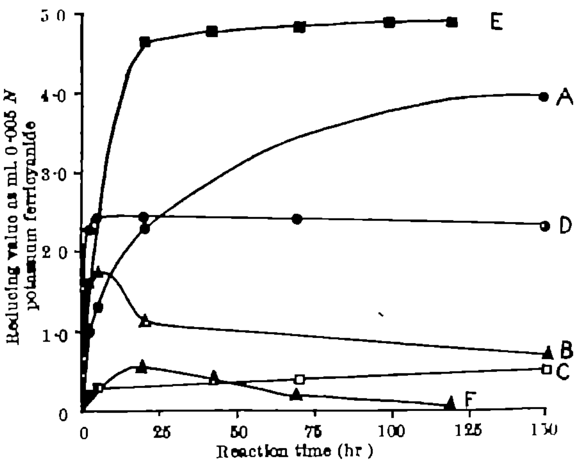
The uronides produced have been separated by paper chromatography using ethyl acetate - acetic acid - water mixtures. Using the original solvent mixtures of Jermyn and Isherwood[1], galacturonic acid and four spots, *A*, *B*, *C* and *D*, were obtained (*R* values for galacturonic acid 1·00, 0·80, 0·58, 0·33 and 0·11 respectively). Each spot reacted as an acid when the dry chromatogram was sprayed with bromophenol blue, and as a reducing substance when treated with *p*-anisidine hydrochloride. By increasing the acetic acid content of the solvent, four other uronides larger than *D* were resolvable. Substances *A* and *B* which occur only in small amounts and have a transitory existence have not yet been identified. Jermyn and Tomkins[2], in a chromatographic study of pectic enzyme action, demonstrated the formation of a series of uronides. An examination of a *Botrytis* bran culture from Dr. Tomkins indicates that *C* and *D* are the same as the 'di-' and 'tri-uronides' of Jermyn and Tomkins.

The calcium salts of uronides *C* and *D* are precipitated by 60 per cent ethanol and can be obtained free from galacturonic acid. The lead salt of *C* is appreciably soluble in water, the lead salt of *D* is insoluble and a separation can thus be achieved. Preliminary studies of the reducing value of *C* and *D* by the alkaline hypoiodite method indicate they are the di- and tri-uronides. A recent paper[1a] shows that a polygalacturonase type enzyme from a yeast produces two compounds with properties similar to *C* and *D*.

The action of (*S*) preparations on pectic acid is characterized by a rapid liberation of reducing groups, with the simultaneous destruction of the colloidal properties of the substrate ; the reaction curve then shows a sharp change to a slower rate. In the initial rapid phase, a mixture of uronides not resolvable upon the chromatogram is produced, and these are then degraded to a mixture in which galacturonic acid and *C* and *D* predominate. In the second, slower, phase of the reaction, *C* and *D* are completely converted to galacturonic acid. With (*D*) preparations, the large uronides first formed are converted to a mixture containing only *C* and *D*, with small amounts of galacturonic acid ; the reaction then ceases, although enzyme active against pectic acid is still present.

For chromatographic analysis, 0·05 ml. aliquots of enzyme substrate mixture were run in duplicate together with duplicate galacturonic acid markers on Whatman No. 1 paper with ethyl acetate - acetic acid - water mixtures for 18 hr. Papers were dried in air, sprayed with bromophenol blue, and appropriate spots dissected, eluted into dilute alkali and estimated by the micro-ferricyanide method. Reducing value of galacturonic acid markers : recovered 95–102 per cent ; reducing value of uronides + galacturonic acid recovered in Exps. 1–3, 95 per cent.

The marked difference between the action of (*D*) and (*S*) preparations may be seen from quantitative chromatograms (see diagram). In Expt. 2, only uronides *C* and *D* and galacturonic acid were detectable in the 20-hr. chromatogram. In Expts. 1 and 2, the amounts of the (*S*) and (*D*) preparations were selected so that their activities on the colloidal properties of pectic acid were the same, that is, their activities were equal both by 'cup-plate'[3] and viscometric[4] methods. Higher concentrations of the (*S*) preparation, Expt. 3, resulted in a more rapid conversion of pectic acid to galacturonic acid. From the action of (*D*) preparations on pectic acid, samples containing only *C* and *D* were obtained in a yield equivalent to 75 per cent of the uronic anhydride content of the original substrate, and the mixture of *C* and *D* was completely converted to galacturonic acid by (*S*) preparations at a *p*H optimum of approximately 3·5.



Chromatographic analysis of the action of (*D*) and (*S*) type preparations on sodium pectate at *p*H 5·3.

Expt. 1 Action of 50 mgm. (*S*) type preparation on 50 ml of 2 per cent sodium pectate. *A*, Galacturonic acid produced, *B*, higher uronides produced

Expt. 2. Action of 800 mgm. (*D*) type preparation on 50 ml of 2 per cent sodium pectate. *C*, Galacturonic acid produced, *D*, higher uronides produced.

Expt. 3 Action of 800 mgm. (*S*) type preparation on 50 ml. of 2 per cent sodium pectate. *E*, Galacturonic acid produced *F*, higher uronides produced

Polygalacturonase[5] has been postulated as an enzyme degrading pectic acid to galacturonic acid, and chromatographic evidence[6] appeared to support this view. From the present findings, it is clear that the degradation of pectic acid to galacturonic acid involves at least two enzymes. One of these (I) degrades pectic acid to uronides *C* and *D*, and another, (II), is necessary to convert these uronides to galacturonic acid. The (*D*) preparations consist of the former enzyme, and (*S*) preparations (and various commercial samples examined) are mixtures of the two. It is not known whether the enzyme (II) attacking the uronides *C* and *D* can also degrade higher uronides, and it is not therefore possible to define assay methods for enzymes (I) and (II). However, by carrying out parallel assays with both pectic acid and a mixture of *C* and *D* as substrates, it can be shown that (*D*) preparations attack pectic acid only, whereas (*S*) preparations attack both substrates ; but the ratio of the two activities varies widely with the preparation.

The (*D*) preparations, when heated at 100° C. in 10 per cent w/v magnesium chloride for 10 min., retain about 30 per cent of their activity, and in their thermostability resemble the pectic 'depolymerase' of tomatoes[6]. A 'depolymerase' isolated from *Neurospora*[7] has similar properties to the (*D*) preparation. Barratt (personal communication) has shown by paper chromatography that a number of uronides accumulate during the action of the *Neurospora* enzyme. A *Neurospora* preparation from Dr. Barratt was compared in these laboratories with a purified

(*D*) preparation. The preparations had equal activities by the 'cup-plate' assay and both rapidly reduced the viscosity of pectic acid; but whereas the action of the (*D*) preparations was practically complete in 4 hr., the *Neurospora* preparation produced in this period a mass of uronides which could not be resolved on the chromatogram; after 18 hr. the reaction products were partially resolvable and small amounts of uronide *D* appeared, but it was eight days before complete conversion to uronides *C* and *D* and galacturonic acid was obtained. These results suggest that the destruction of the colloidal properties of pectic acid and the formation of uronides *C* and *D* are not accomplished by the same enzyme.

A study of the structure of uronides *C* and *D* is in progress, and this, together with the properties of the enzymes, will be reported when completed.

Thanks are due to the directors of H. W. Carter and Co., Ltd., for permission to publish these results, to Dr. Tomkins for a sample of *Botrytis* bran and to Dr. Barratt, who kindly sent us prior to publication the manuscript of a paper on the 'depolymerase' of *Neurospora* and a sample of this enzyme. [May 16.

Note added, October 22. The (*D*) preparations contain two enzymes. The *p*H-activity curves of these preparations on pectic acid show two optima, at *p*H 5·3 and at 3·5. The former peak is due to enzyme (I*a*) which may be inactivated at *p*H 5·0 and 50° C. for 30 min., and attacks pectic acid and pectin (without simultaneous demethylation) with a rapid destruction of the colloidal properties of the substrate and the formation of a "low molecular weight polyuronide"[7]. The peak at *p*H 3·5 is given by enzyme (I*b*), which attacks pectic acid and lower demethylated uronides with a slow destruction of the colloidal properties and a rapid liberation of galacturonic acid and uronides *C* and *D*. Whereas the concentration of enzyme (I*a*) is approximately equal in the (*D*) and *Neurospora* preparations used above, the content of (I*b*) in *Neurospora* is only 5 per cent of that in the (*D*) preparation.

Through the courtesy of Dr. H. J. Phaff we have shown that *C* and *D* are chromatographically identical with his di- and tri-galacturonic acids. (A. P., W. W. R., G. L. S.)

STREAMING POTENTIAL AND ELECTRO-OSMOSIS

A Model for the Mechanism of Streaming Potential

ALTHOUGH considerable efforts to explain experimental phenomena on the basis of the classical theory of streaming potential have been made, it would appear that the model upon which the theory is based is defective. A more comprehensive theory might possibly be based upon a model described here. In this model it is postulated that: (1) the radial distribution of charge varies smoothly along the capillary during steady-flow conditions; (2) there is no circulation of ions within the fluid.

These postulates are deduced from the following experimental observations. (*a*) A system comprising an arrangement of solid–liquid interfaces at rest is, as a whole, electrically neutral. (*b*) A (thermodynamic) potential generally exists at solid–liquid interfaces and can be detected with a standard electrode. (*c*) Relative movement between solids and liquids is generally accompanied by the setting up of a potential difference along the direction of flow. (*d*) This potential difference tends to a steady value for a given set of flow conditions.

Thus, since a capillary full of liquid receives no charges from outside the system, it follows that any electrical effects during liquid flow must arise from a re-distribution of charges which are present in the stationary state.

In order that any electrical effect may arise, there must be an initial radial distribution of charges in the stationary condition which is disturbed by the onset of liquid flow. This radial distribution can arise in three ways: a transfer of charge from the surface to the liquid; a transfer of charge from the liquid to the surface; an exchange of charges between the liquid and solid. When equilibrium is reached after the separation of charges, the radial distribution of charge within the liquid is determined by a balance of the forces acting on the ions, as a result of the interaction between the ions and the charged wall and the mutual interaction between the ions, the form of the distribution being in accordance with the equations of Poisson and Boltzmann. Axial flow of the liquid within the tube, under the influence of a hydraulic gradient, will tend to strip the diffuse layer at the inlet end of the capillary. The parabolic distribution of flow velocity will cause the rate of removal of charge to vary with the radius, so that a tapering of the diffuse layer will occur along the length of the tube.

Since it is known that the streaming potential reaches a steady value for a given set of flow conditions, it follows that the stripping of the diffuse layer must be counterbalanced by a restoring action. It also follows, from the constancy of the streaming potential, that, for steady conditions, the liquid flowing through the tube must be electrically neutral.

For the present purpose it is postulated that the layer is restored by both the following mechanisms: (1) Under the influence of the axial potential gradient, the ions in the body of the incoming liquid are dependent upon the sign of the charge these carry, either accelerated or decelerated, the unbalanced surplus of one sign so formed being dispersed by radial migration under the influence of the radial potential gradient and inclusion in the diffuse layer. (2) The transfer mechanism at the interface operates to replace the lost charges towards the inlet end of the tube and in the opposite direction towards the outlet end. Thus, over the whole surface of the tube, equal numbers of charges are entering and leaving the wall layer. The present analysis requires the simultaneous operation of both these mechanisms, but does not exclude the possibility of others.

Detailed analysis based on this model shows that

(1) The model leads to an expression dependent on the same variables as the classical equation.

(2) The four common electro-kinetic effects, streaming potential, electro-osmosis, cataphoresis, and sedimentation potential, can be explained.

(3) The special conductivity K_s substituted by Briggs[1] in the classical equation in place of the bulk liquid conductivity is justified.

(4) Possibly (*a*) flocculation and (*b*) dispersion may be explained on this basis.

(5) The observations of Casagrande[2] on the pressure effects arising from electro-osmosis can be explained.

(6) Deviations from Darcy's law observed by various workers can also be explained on this basis.

Acceptance of the model also leads to the conclusion that the term 'zeta potential' has no rigid meaning; and analytical treatment of streaming potential along the lines followed by Elton[3] requires reconsideration.

A full account of the work will be published elsewhere.

Mechanism of Electro-osmosis

As indicated above, the Rose and Moss model of ionic distribution for steady streaming potential conditions suggests a similar mechanism for electro-osmotic flow.

The application of an electrical potential gradient along the length of the capillary will disturb the ionic distribution of the diffuse double-layer, at rest, resulting in a thinning down of the layer towards the inlet end of the capillary. The double-layer will be partly restored by ions of the same sign contained in the incoming liquid, and when steady flow conditions are reached, the radial distribution of ions will vary along the length of the tube. The ions of the removed double-layer are discharged at the down-stream electrode while the ions in the incoming water of opposite sign to the diffuse double-layer are discharged at the other electrode, these two ionic streams composing the current concerned in electro-osmosis as distinct from the ordinary galvanic current in the capillary. The ionic force available in the double-layer for overcoming the viscous shear resistance of the double-layer in electro-osmotic flow is proportional to the ionic concentration of the double layer. In the suggested mechanism, the variation of ionic concentration along the length of the capillary means that the ionic tractive force will also vary along the capillary, being a minimum at the inlet end.

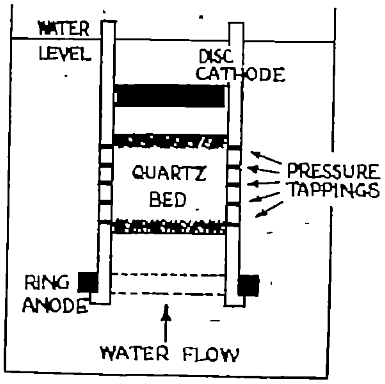

Fig. 1. General layout

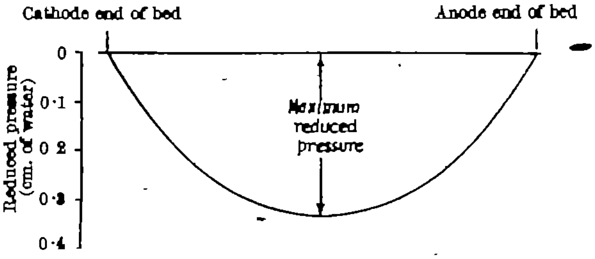

Fig. 2. Distribution of reduced pressures within the bed

From considerations of flow continuity, the rate of liquid flow will be dependent on the mean force available in the capillary. At any point along the tube the tractive force available will differ from the mean ionic tractive force by a certain amount, and a compensating pressure gradient will be induced at that point, the size and direction of which will depend on this difference.

In streaming potential there is no removal of charge from the system, and the solid – liquid system remains electrically neutral, whereas in electro-osmosis it would be expected that the solid – liquid system should contain a deficiency of the ions of the kind forming the double-layer.

Experimental work. Experimental work has been carried out on electro-osmotic flow of distilled water through a bed of quartz powder of size ranging from 50 μ to 140 μ subject to potential gradients of up to 40 volts/cm. Measurements of electro-osmotic discharge of water and of pore-water pressures within the bed were made with no external hydraulic pressure gradient across the bed. The general layout is shown in Fig. 1.

Pressures below that of the free water at either end of the sample were measured in the bed, the distribution of these reduced pressures being of the form shown in Fig. 2, with the greatest pressure reduction occurring near the centre of the length of the bed.

A typical result was that a maximum pressure reduction was obtained near the centre of the bed of 0·33 cm. of water in a quartz bed of 4·67 cm. length under a potential gradient of 21·7 volts/cm., giving a discharge of 1·95 × 10^{-3} c.c. of water per sec. per sq. cm. of bed.

The observed distribution of pressure within the bed agrees with the suggested theory, as the tractive force would be a minimum at the inlet end of the bed (the anode end for a quartz-distilled water system) and therefore less than the mean force governing the rate of flow. A supporting or assisting pressure gradient would consequently be expected towards the inlet end of the bed, reaching a maximum value at that end of the bed, which is indeed observed in the tests. Similarly, the negative or resisting pressure gradient measured towards the outlet end of the bed would be predicted from the theory.

Temperature of the Interior of the Earth

BULLEN[1,2] has derived both the density and the compressibility of the earth as functions of depth, and has found that the bulk modulus k, which is the reciprocal of the compressibility $\varkappa$, is a linear function of the pressure p:

$$k = k_0 + ap. \qquad (1)$$

Ramsey[3] has re-examined this relation from the point of view of the theory of solids, and his conclusions agree with those of Bullen, namely, that the linear relation (1) is valid both in the core and in the mantle below 1,000 km. Ramsey, however, found that the constant k_0 had different values in the core and mantle, although the derivative $dk/dp = a$ was sensibly the same.

In view of equation (1), it seems reasonable to suppose that a similar relationship exists between the volume coefficient of thermal expansion α and pressure p, namely, that the reciprocal of α is a linear function of p:

$$\frac{1}{\alpha} = \frac{1}{\alpha_0} + bp. \qquad (2)$$

In a recent investigation on the thermal properties of the earth (based on the theory of solids), Uffen[4] has obtained values of α within the mantle, and it is found that they are in excellent agreement with hypothesis (2). It is assumed that the relation (2), like the relation (1), is valid both in the core and the mantle. The values of the constants $1/\alpha_0$ and b are found to be:

$$1/\alpha_0 = 2\cdot4 \times 10^4 \,°\text{K.}, b = 6\cdot2 \times 10^{-8} \,°\text{K. cm.}^2/\text{dyne}. \qquad (3)$$

A theoretical investigation for the justification of (2) is in hand.

It is now possible to make an estimate of the adiabatic temperature gradient throughout the earth. The adiabatic gradient may be written

$$\frac{dT}{dp} = \frac{\alpha T}{\rho c_p}, \qquad (4)$$

where ρ is the density and c_p the specific heat at constant pressure. From (2) and (4),

$$\frac{dT}{T} = \frac{dp}{\rho c_p\left(\frac{1}{\alpha_0} + bp\right)}. \qquad (5)$$

Both Uffen[4] and Verhoogen[5] obtained values of the ratio α/c_p in the mantle using seismic data. Uffen found that the values of c_p were approximately constant (in agreement with Bridgman's observations at relatively low pressures), and that the variations in α/c_p were almost entirely due to variations in α. A constant value for c_p is assumed, so that from (5),

$$\ln T = \frac{1}{c_p}\int \frac{dp}{\rho\left(\frac{1}{\alpha_0} + bp\right)} \qquad (6)$$

It is estimated that variations in c_p will not affect the validity of (6) by more than 5 per cent. Since ρ is known as a function of depth (and hence of pressure), equation (6) can be integrated numerically. Hypothesis (2) is assumed to hold at all depths below 1,000 km., although preliminary investigations show that it is not likely to be much in error up to depths of 500 km. Taking T at 1,000 km. to be 3,600° K. (Uffen[4]), values of T can be estimated at all greater depths. It is found that the temperature at the boundary of the core and mantle is 4,350° K. and at the centre of the earth a little greater than 4,800° K. The increase throughout the core is thus only 500°. The results should be of considerable interest to Bullard's[6] theory of the transfer of heat from the core. Further implications of equations (1) and (2) are being investigated, and it is hoped to publish a fuller account elsewhere.

Effect of Water Vapour on Explosions of Carbon Monoxide

IT is well known that the low-pressure explosion of carbon monoxide – oxygen mixtures is characterized by an upper and a lower pressure limit of explosion at a particular temperature. We find that it is also characterized by an upper and a lower pressure limit for a glow, accompanied by slow oxidation, to occur.

Garner and Gomm[1], Cosslett and Garner[2] and Hadman, Thompson and Hinshelwood[3] found water vapour to have no effect on the lower explosion limit. In accordance with this, we find that water vapour has no effect on the lower glow limit. Hadman *et al.*[3] also concluded that water vapour had no effect on the upper explosion limit. We cannot confirm this conclusion. Water vapour raises both the upper glow limit and the upper explosion limit. As a consequence it reduces the temperature of the tip of the explosion peninsula.

Hadman *et al.*[3] made their statement because, using a dry mixture and a static method, they obtained the following values for the upper explosion limit:

650° C.	67 per cent O_2.	P = 240 mm
680° C.	67 „ „ O_2.	P = c. 360 „

and compared these values with the following, obtained by Kopp, Kowalsky, Sagulin and Semenoff[4], using a wet mixture and a flow system:

650° C.	90 per cent O_2.	P = 260 mm
	33 „ „ O_2.	P = 190 „
680° C.	33 „ „ O_2	P = c. 400 „

The comparison, made in 1932, is scarcely very satisfactory. The agreement is neither extensive nor exact. The comparison ignores any possible difference in results for flow and static systems. Examples are known where ignition temperatures determined in flow systems have been high relative to determinations in static systems. Nevertheless, the statement that water vapour has no effect on the upper explosion limit has been repeated as a fact right through the literature down to the present time (for example, ref. 5, p. 208; ref. 6, p. 70; ref. 7, p. 23; ref. 8, p. 78). It appears that from 1932 to the present study no one set of investigators has carefully determined the upper explosion limit in both wet and dry mixtures and under otherwise similar conditions.

In the literature prior to 1932, there are several observations which should have warned workers against accepting the conclusion of Hadman *et al.* Dixon[9], long ago, found that water vapour has a sensitizing effect on the spark ignition of carbon monoxide – oxygen mixtures at atmospheric pressure. Prettre and Laffitte[10] showed that addition of 5 per cent water vapour lowered the spontaneous ignition temperature at atmospheric pressure by 20°–30° C. Observations by Topley[11] contain a clear statement that the upper pressure limit of explosion depends upon the concentration of water vapour, and an implication that water vapour reduces the temperature of the tip of the explosion peninsula. Topley's work, however, has been completely neglected.

We should also like to mention that we have found the explosion peninsula of carbon monoxide to be expanded by small, and contracted again by large, quantities of methane. A full account of these and other observations relating to the combustion of carbon monoxide will be published elsewhere.

Note added in proof. Since this letter was submitted for publication, we have learnt that Dr. A. S. Gordon (*J. Chem. Phys.*, 20, 340; 1952) has also found water vapour to have a marked effect in raising the upper explosion limit.

Poisoning of Oxide Cathode Emission by Oxygen

THE following experiments were carried out in an attempt to determine the mechanism of the reduction of electron emission from oxide cathodes by oxygen.

Metson[1] demonstrated the reversibility of oxygen poisoning, and suggested that a possible recovery mechanism was the outward diffusion of negative oxygen ions after a poisoning attack. An attempt was therefore made to detect directly any change in the emission of oxygen ions after poisoning by using a mass spectrometer with an oxide cathode source.

The emission from mixed barium and strontium oxide cathodes at temperatures in the range 1,000°–1,200° K. was reduced to 10 per cent of its initial value by liberation of oxygen from a heated tungsten wire coated with barium peroxide. After the oxygen flow was cut off, the emission of both electrons and negative oxygen ions was studied. The following points were noted.

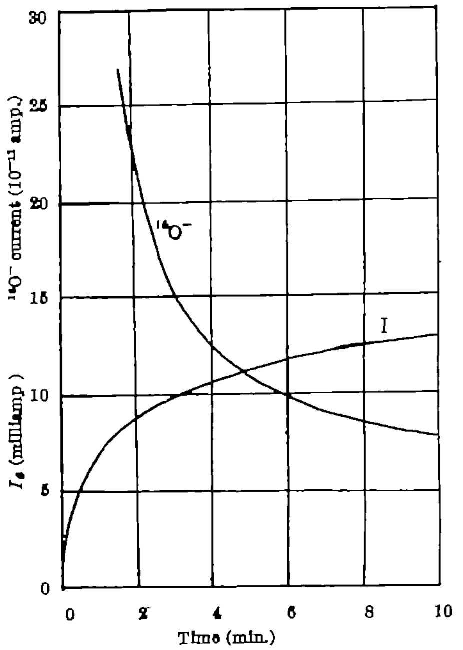

Fig. 1. Typical curves showing variation of oxygen ion current ($^{16}O^-$) and electron emission I with time, during recovery from an oxygen poisoning attack

(1) The poisoning phenomenon was completely reversible, that is, full recovery of electron emission to its initial value occurred, even after several previous attacks.

(2) The emission of ionized oxygen from the cathode increased, often by a factor of 10 or more, immediately recovery commenced, gradually falling off to its original intensity as recovery was completed (see Fig. 1). The predominant oxygen ion was that of mass 16, although traces of the ion oxygen-32 sometimes occurred.

(3) Higher activation-rates existed in the presence of larger potential gradients in the cathode coating.

(4) Poisoning experiments at varying temperatures showed: (*a*) increased sensitivity to poisoning at low temperatures; (*b*) considerably higher rates of oxygen evolution during recovery at higher temperatures.

(5) Energy distribution measurements on the oxygen ions showed that those emitted during normal operation of the cathode were characterized by the possession of energies in excess of the spectrometer accelerating voltage, suggesting formation by bombardment of a surface film of oxygen by high-energy positive ions formed in the electron gun[1,2]. Those emitted after poisoning, however, had their origin in the cathode coating itself. These results may be explained by the assumption that, on poisoning, the oxygen enters the cathode coating, reducing the emission by either (*a*) the formation of surface oxygen films on the emitting oxide crystals, or (*b*) the occupation of vacant oxygen sites (especially near-surface sites) in the oxide crystal lattice.

To determine the relative importance of the two processes under various conditions, further experiments were carried out on the effect of oxygen on electron emission and coating conductivity using

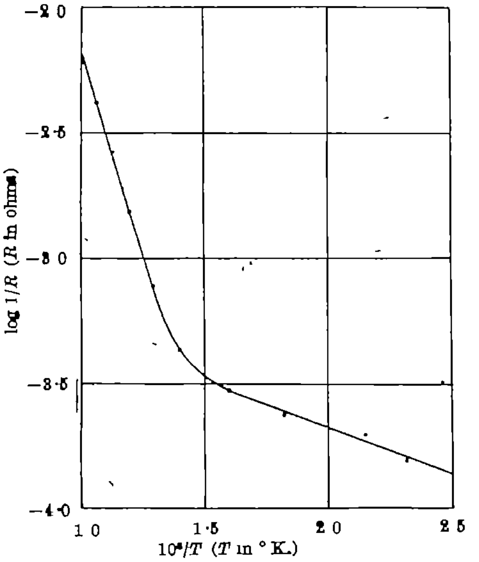

Fig. 2. A plot showing the variation of conductivity of the cathode coating with temperature T. R is the resistance of the coating

low-voltage cylindrical diodes. These valves had mixed barium and strontium oxide cathode coatings of thickness 50–100 microns with a helical nickel probe wire of diameter 0·0125 mm. embedded in the oxide layer. Conductivity measurements were made by applying up to 100 mV. between probe and base metal, in both directions. The experiments showed:

(1) Completely ohmic current-voltage characteristics providing that both cathode base metal and probe wire were efficiently treated in a hydrogen furnace to remove surface oxide films, etc., before assembly.

(2) The variation of coating conductivity with temperature T gave plots of log $1/R$ against $1/T$ consisting of two straight lines, showing the presence of two conduction processes with a transition temperature of about 700° K. in all tubes used (see Fig. 2). The low-temperature activation energy was about 0·1 eV., whereas the high-temperature activation energy was 0·8 eV. This may be explained by the suggestion of Loosjes and Vink[4] that the two processes involved are (*a*) a crystal-to-crystal conduction process, predominating below 700° K., and (*b*) a process of electron emission and absorption across the inter-crystal spaces, predominating above 700° K.

(3) On investigating the effect of oxygen on emission and conductivity, the following facts emerged: (*a*) at temperatures above 700° K., the conductivity of the coating and the electron emission were poisoned by oxygen in the same way; (*b*) at temperatures below 700° K., the conductivity was scarcely affected by the introduction of oxygen into the cathode coating, even though the electron emission was reduced to one tenth of its original value.

It seems probable, in view of the above results, that the main cause of oxygen poisoning is the adsorption of thin films of oxygen on both the outer cathode surface and the interior crystallite surfaces, reducing both emission and conductivity of the coating at high temperatures. At low temperatures, such adsorption will reduce the emission from the outer surface without appreciably affecting the conductivity of the coating, since the main contribution is by direct crystal-to-crystal conduction at temperatures below 700° K.

The experimental work was carried out in the Physical Laboratories of the University of Manchester, and I wish to thank Prof. P. M. S. Blackett and Prof. F. A. Vick for facilities and help.

A complete report on the above work is in course of preparation for publication.

Coloured 'Perspex' for Darkroom Lights

King and Ventura[1] have recently directed attention to the value of coloured 'Perspex' in the construction of filters for colorimetry, and it may be of interest to describe a similar use to which this material hac been put in this laboratory.

Experimental botanists frequently require ε 'physiological darkroom' in which plants and culture may be grown with minimum disturbance from light. In practice, this amounts to employing weak, phototropically inactive light, which is commonly obtainec by screening the unwanted wave-lengths from ordinary incandescent bulbs. Coloured glass obtainec from glaziers seldom possesses the required transmission, and although special dyed-in-the-mas glasses are obtainable from scientific glass makers they are (in some countries) difficult to obtain, anc relatively expensive in the size required. Red 40 and Amber 300 'Perspex' have been successfull used in place of glass.

Transmissions over the relevant spectral regions determined by a model *DU* Beckman spectrophotometer for sheets ⅛ in. in thickness, are recorded i the accompanying table.

Wave-length (A.)	Transmission (per cent)	
	Red 400	Amber 30
5260		0·02
5360		1·5
5400		6·5
5460		26·3
5500	0·0	41·8
5800	0·0	87·1
5900	4·3	89·0
6000	24·0	89·5
6250	82·4	
6500	90·4	92·0
7000	92·0	92·3

Although there is evidence[2] for some phototropi response of chlorophyll-containing tissues to ligh of wave-lengths greater than 6500 A., wave-length greater than 5500 A. are usually accepted as bein phototropically inactive to etiolated material. Th most careful determination appears to be that c Johnston[3] working with coleoptiles of *Avena sativa* I var. Culberson. He found phototropic sensitivity t be low at 5000 A.; but the threshold was not reache until 5461 A.

Red 400, which produces a light in which visu acuity is moderately satisfactory, should thus be qui safe for such material; but this would not be e pected of Amber 300, which produces a light providin much easier working conditions. However, coleoptil of *Avena sativa* L. var. Victory have shown no phot tropic response to incandescent light screened throug either Red 400 or Amber 300. Coleoptiles of vario ages have been exposed for periods ranging from a few minutes to 18 hr., the intensity of radiation of the red light being of the order of 4 ergs/mm.²/sec., and that of the amber light 7 ergs/mm.²/sec. It may be pointed out that the Schott filter *OG*-2 is recommended for such a purpose[4], and this filter has a transmission of 14 per cent at 5460 A.

The characteristics of Red 400 and Amber 300, taken together, are of further interest in connexion with a technique recently devised by Heath[5] for taking a series of shadowgraphs of *Avena* coleoptiles. Heath employed Kodak *RP15* 'Reflex' paper, and orange or orange-red cellulose acetate filters for producing the exposing light. The same result can be obtained more conveniently with the above 'Perspex' filters and ordinary bromide paper, since the latter is virtually insensitive to light screened through Red 400, which may therefore be used generally in the room for culture, manipulation, etc., and adequate shadowgraphs can be obtained using light screened through Amber 300 without affecting the plants. Exposures for 2 min. at the intensity recorded above are satisfactory.

The findings discussed here apply to plants cultured in red light (wave-length greater than 6000 A.) at intensities of the order of 5–15 ergs/mm.²/sec.

A word of caution should perhaps be added regarding the permanence of such filters. The manufacturers state that, after 12-months exposure outdoors, "very slight fading" occurred[6]. Insufficient experience has been gained under the conditions of an *Avena* test room (25° C. and 90 per cent relative humidity) to assess deterioration. Possibly, any deterioration could be retarded by mounting the 'Perspex' between sheets of plain glass.

Enzymic Splitting and Synthesis of Glutathione

THE mechanism of the activation of the enzymic splitting of glutathione by glutamine—first considered specific for the amide[1]—may be interpreted as the transfer of the glutamyl moiety from glutathione to glutamine with the formation of the corresponding γ-glutamylglutamine[2,3]. Since it was considered possible that the γ-glutamylglutamine formed from glutathione and glutamine may serve as substrate for glutamotransferase, which can utilize glutamine only[4-9], a detailed study of the activation of the enzymic splitting of glutathione by L-amino-acids and peptides as well as of the effect of γ-glutamyl peptides on the splitting was undertaken. In the experiments to be reported, an extract from sheep kidney, purified by butanol treatment[10] and ammonium sulphate fractionation, served as source of the enzymes. In a similar manner potent enzyme solutions were prepared from brain cortex and liver.

In a representative experiment 6 micromoles of glutathione were incubated with 27 micromoles of the activator to be tested and the enzyme solution (20 μgm. of protein), at *p*H 8·5, in the presence of cyanide, in a total volume of 2 c.c. The liberation of cysteinylglycine was measured by the Sullivan reaction[1]. The initial rates of the splitting of glutathione as activated by various amino-acids and peptides were compared with the activation effected by glutamine, to which a value of 100 was assigned arbitrarily. Glycine, glutamic acid, asparagine, tyrosine, phenylalanine, and glycylglycylglycine activated slightly (0–30), whereas structural analogues of glutamine such as γ-ethylglutamate, methionine, ethionine, and homocysteine proved to be more efficient than glutamine (120–210) (cf. ref. 4). Of equal potency as activators were peptides of glycine in which this amino-acid, as in cysteinylglycine, was substituted in its amino-group (glutaminylglycine, alanylglycine, asparaginylglycine, leucylglycine), whereas dipeptides containing glycine substituted in the carboxyl group were weak activators (glycylglutamine, glycylasparagine, glycylleucine). Glycylglycine as well as glycylalanine—the latter being an exception to the above-described observation—proved to be potent activators of glutathione splitting (220).

When γ-glutamylglycine or γ-glutamylglutamic acid in an amount equal to that of glutamine was added in an experiment in which the amide was used as the activator, much lower colour equivalents in the Sullivan reaction were obtained at the end of the incubation than in control experiments in which no γ-peptide had been added. That we were not dealing with a competitive inhibition of the splitting of glutathione was demonstrated by the observation that the addition of a γ-glutamyl peptide, after incubation of glutathione, glutamine, and enzyme, led to a decrease of the Sullivan reaction of the incubated mixture upon further incubation. The appearance of glutathione, as measured by the glyoxalase test[11], with a simultaneous decrease in the Sullivan reaction, could be demonstrated upon the incubation of cysteinylglycine, γ-glutamylglycine, and enzyme (see table). The discrepancy between the amount of cysteinylglycine disappearing (Sullivan) upon the incubation of the dipeptide with glutamylglycine and the amount of glutathione formed (glyoxalase) is striking. The reasons for this discrepancy may be found partly in the inhibition of the utilization of glutathione in the glyoxalase test by cysteinylglycine, and partly in the conversions which glutathione undergoes under the action of enzymes which deprive it of its ability to activate glyoxalase without concomitant liberation of cysteine or cysteinylglycine. The results, although only of a qualitative nature, show that glutathione may be synthesized from γ-glutamylglycine and cysteinylglycine by an exchange reaction between the two peptides. Cysteinylglycine proves, therefore, to be as effective an acceptor of the γ-glutamyl radical as the other peptides in which the amino-group of glycine is substituted (see above). The synthesis of glutathione by an exchange reaction is of particular interest since the tripeptide can also be synthesized from the component amino-acids with the participation of

adenosine triphosphate[12], this synthesis consisting in the addition of glycine to γ-glutamylcysteine which is formed first[13]. Whether the synthesis of glutathione by an exchange reaction indicates an alternate pathway or the last step of the synthesis of the tripeptide with the participation of adenosine triphosphate may be decided by study of the respective enzyme preparations.

The experiments show that the transfer of the glutamyl radical is not a property of glutathione alone, but also of other γ-glutamyl peptides (cf. ref. 2*b*). The question arises whether the presence of free γ-glutamyl peptides other than glutathione has escaped discovery because of the lack of an easily detectable functional group or because of their rapid metabolic utilization. It can be visualized that the substitution of an amino-acid in its α-amino-group by a γ-glutamyl radical modifies the properties of the amino-acid in such a way that it may either undergo further synthetic reactions by enzymically catalysed exchange, or is enabled to condense its free α-carboxyl group with the amino-group of another amino-acid with participation of adenosine triphosphate (cf. ref. 14).

This work has been carried out in part under grants from the Rockefeller and the National Vitamin Foundations, and under a contract between the Office of Naval Research and the New York State Psychiatric Institute.

Essential Role of Thiol Groups in Carboxylase

ESSENTIAL thiol groups of enzymes are usually detected by the inactivation of the enzyme with sulphydryl reagents, such as substances forming mercaptide, or oxidizing or alkylating substances[1]. Yeast carboxylase seems to be affected in a rather uneven and contradictory way by sulphydryl group detectors since 4-aminophenyldichloroarsine[2], *p*-chloromercuribenzoate[3], iodine[3], iodoacetate[3], cupric[3,4], mercuric and silver ions[4], or quinone[5] inhibit the enzyme, while in other experiments, lewisite oxide[6], ethylarsenoxide[7], iodoacetate[4] or ethyl iodoacetate do not modify its activity significantly. It must be pointed out: (*a*) that inhibition by a single thiol reagent does not prove the existence of sulphydryls since even very selective mercurial compounds[9] can inactivate enzymes which by other evidence do not seem to contain essential thiol groups; and (*b*) that the effect of sulphydryl detectors often depends on the purity of the enzyme preparation tested[10], a circumstance neglected in some of the work quoted Therefore, considering the essential part played by thiol groups in most of the enzymes related to pyruvate metabolism[2], it seemed interesting to make a systematic study of the action of several types of thiol reagents on a conveniently purified carboxylase, and for that purpose we have used the preparation described by Green *et al.*[4] (Q_{CO_2} about 12,000).

The activity of carboxylase dissolved in 0·05 *M* phosphate buffer pH 6·0 at 30°, measured manometrically, diminishes by 50 per cent after 15 min incubation with any of the following inhibitors 5·0 m*M* methylarsenoxide; 0·8 m*M* mapharside (3-amino-4-hydroxyphenylarsenoxide hydrochloride) 1·4 μ*M* *p*-chloromercuribenzoate; 1·4 μ*M* mercury (Hg^{++}); 2·5 μ*M* silver (Ag^{+}); 0·44 m*M* copper (Cu^{++}); 2·0 m*M* iodoacetate; 9·7 m*M* ethy iodoacetate; 1·4 m*M* bromobenzylcyanide; greater than 10·6 m*M* chloroacetophenone (highest concentration obtained); 12·5 m*M* alloxane and 1 0 m*M* *o*-iodosobenzoate. Lachrymators, like ethy iodoacetate and chloroacetophenone, affect the activity of carboxylase less than pyruvate oxidative decarboxylation by living cells of *Saccharomyces cerevisiae*[11], and they are the slowest reacting of al the inhibitors tested. The effect of the arsenicals i not reversed by dilution and does not depend on the amount of carboxylase present, while inhibition by heavy metals (and *p*-chloromercuribenzoate) i not reversed by dilution, but depends on the enzyme concentration and may be described as pseudo irreversible, following the definition of Ackerman and Potter[12].

Cysteine, glutathione or 2 : 3-dimercaptopropano (*BAL*) can modify the inhibition of carboxylase by thiol reagents. Thiols protect carboxylase from inactivation by methylarsenoxide and mapharside 2 : 3-dimercaptopropanol being more effective tha cysteine or glutathione against methylarsenoxide; a regards mapharside, however, cysteine is more effective than 2 : 3-dimercaptopropanol. After inhibitio with the arsenicals, carboxylase can be activated wit thiols. 2 : 3-Dimercaptopropanol reduces significantl methylarsenoxide or mapharside inhibition (91·0 an 45·0 per cent, respectively), while an amount o cysteine or glutathione containing an equivalen amount of sulphydryl (As : SH ratio of 1 : 15 mol only diminishes the effect of methylarsenoxid to a smaller degree (40·0 per cent). The toxicity o

* Carboxylase was mixed with the inhibitor and incubated at 30° for 15 min. before adding 0·1 ml. *M* pyruvate

heavy metals is prevented and almost completely reversed by thiols. 2 : 3-Dimercaptopropanol is more effective than cysteine against cupric or mercuric ions, but their action is similar against *p*-chloromercuribenzoate or silver (Ag^+). Cysteine completely prevents carboxylase inactivation by iodoacetate or ethyl iodoacetate, provides partial protection against chloroacetophenone or bromobenzylcyanide, but does not affect the toxicity of the alkylating agents once they have reacted with the enzyme.

The reversal of the inhibition induced by *p*-chloromercuribenzoate or mercuric ion with cysteine or glutathione enables one to show that both inhibitors, the arsenical compounds *o*-iodosobenzoate and iodoacetate, react with the same group of carboxylase. If the enzyme inhibited by mercuric ions or *p*-chloromercuribenzoate is treated with mapharside, iodoacetate or *o*-iodosobenzoate, it can be activated by adding an amount of cysteine or glutathione unable to reverse the inactivation produced by the same concentration of marpharside, iodoacetate or *o*-iodosobenzoate alone.

The action of arsenicals, *p*-chloromercuribenzoate, mercuric ions, cupric ions, iodoacetate or *o*-iodosobenzoate, is greatly diminished or even nullified when they are added to carboxylase in the presence of pyruvate. The effect of pyruvate is proportional to its concentration, as shown in the accompanying table ; and it cannot be replaced by other electrolytes like sodium acetate or chloride. Pyruvate protection against *p*-chloromercuribenzoate or mercuric ions satisfies the equations of competitive inhibition[13], but only for each concentration of inhibitor. Pyruvate interferes with the combination of carboxylase with the inhibitor but does not dissociate the inactive complex, since once the enzyme has reacted with the inhibitor, the addition of any amount of substrate does not reduce the inhibition. Cocarboxylase and/or magnesium do not affect the action of mapharside, heavy metals or iodoacetate.

From this briefly summarized evidence, it may be concluded that the activity of carboxylase depends on thiol groups closely related to the formation of the carboxylase - pyruvate complex, which are extremely sensitive to heavy metals and their compounds, but less reactive to other thiol detectors like trivalent arsenical compounds, alkylating or oxidizing agents. These thiols do not give the Hefter's nitroprusside test and therefore must be considered sluggish reacting groups. Full experimental details of this work will be given elsewhere.

We are indebted to Boots Pure Drug Co., Ltd. (England), and the British Council ; Parke Davis and Co. (U.S.A.) ; and E. R. Squibb and Sons (Argentine) S.A., for kindly supplying samples of pure 2 : 3-dimercaptopropanol, mapharside and 3-amino-4-hydroxyphenyldichloroarsine, respectively.

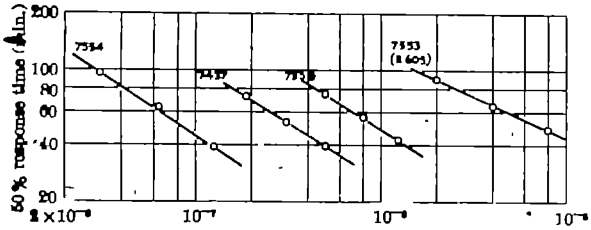
A New Method for the Bioassay of Cholinesterase Inhibitors

Recent studies of the toxicity of anticholinesterase compounds have emphasized the need for a sensitive and reliable method for the biological assessment of their relative activities. We have developed such a bioassay procedure using the freshwater shrimp, *Gammarus pulex* deG.

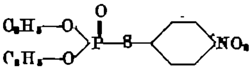
The choice of such an aquatic organism was based on the following considerations : (*a*) the aqueous medium provides a uniform environment and allows of accurate administration of toxic agent ; (*b*) circulation of water through a gill system is likely to facilitate absorption ; (*c*) the presence of a highly organized nervous system is necessary for the development of a well-defined and characteristic response ; (*d*) ready availability, enabling sufficient numbers to be used for statistical significance ; (*e*) robustness and sufficient size to be handled and observed easily.

Investigation of a wide range of candidate organisms led to the selection of *Gammarus pulex* as the most satisfactory. Since an adequate supply of this species is available from local streams, we have not found it necessary to undertake large-scale breeding. Considerable numbers may be kept in shallow trays,



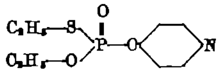
Comparative activity of 'standard Parathion' (E605) with its sulphur isomers and 'toxic batch':

7554.

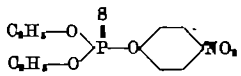


7437, toxic batch

7559.



7553 (E605).



containing not more than one centimetre depth of hard water, for at least a week without deterioration.

A complete test involves the observation of three or more groups of about forty gammarids, each in different dilutions of the toxic agent contained in large Petri dishes and maintained at 21·5° C. For convenience, observations are made at logarithmically separated intervals, and those specimens exhibiting the characteristic response are counted and removed.

The anticholinesterase substances used all produce similar effects, which may be divided into the following phases: (1) an initial phase in which responses appear normal; (2) a phase in which movements, though co-ordinated, are exaggerated; (3) a phase in which the exaggerated movements become inco-ordinated, with characteristic convulsions terminating in dorsal flexure where the concentration of toxic substance is high. This third phase is taken as the response and is followed by: (4) immobility except for the swimmerets and occasional spasmodic leg movements; (5) complete immobility and death.

The 50 per cent reaction-time for each concentration is obtained graphically from a log-normal transformation in which the probit corresponding to the percentage of organisms which have reacted is plotted against the logarithm of the corresponding time interval. This relationship is linear over the significant range between 10 and 90 per cent. When the 50 per cent reaction-time is plotted against concentration on logarithmic co-ordinates, a straight line is obtained, the slope of which is very similar for related compounds (see graph) and which is linear over a very wide range of concentrations.

An interesting application of the method is illustrated in the graph. It was found that certain batches of commercial 'parathion' (consisting mainly of O.O.diethyl O.*p*-nitro phenyl thiophosphate) were several times more toxic to mammals than a standard preparation. Isomerization was suspected, and the two sulphur isomers (O.S.diethyl O.*p*-nitrophenyl phosphate and O.O.diethyl S.*p*-nitrophenyl phosphate) were prepared by the manufacturers and submitted for examination.

The results obtained with the standard 'parathion' (7553), the suspect sample (7437) and the two isomers (7554) and (7559) are shown in the graph. The relative toxicities may be determined from the horizontal separation of the lines, and from these it was possible to confirm that sample (7437), which had a correct 'element' analysis, contained a high proportion of the more toxic isomers.

The systemic insecticide, OMPA (octamethyl pyrophosphoramide), has no action upon *Gammarus*. Dubois *et al.*[2] have shown that it does not inhibit cholinesterase *in vitro*, but is changed to an effective inhibitor by certain plant and animal tissues. Several workers[3] indicate that, in contrast to its sulphur isomers, pure O.O.diethyl O.*p*-nitrophenyl thiophosphate is also a poor inhibitor *in vitro*, but is transformed *in vivo* to an effective inhibitor. This compound, however, is toxic to gammarids.

This bioassay method was first demonstrated at a meeting of the British Pharmacological Society on July 9, 1949. It has been in continuous use for three years and has amply proved its reliability and precision.

Acknowledgment is made to the Chief Scientist, Ministry of Supply, for permission to publish this communication. A fuller account of the work will be published elsewhere.

Pyrolysis of Dissolved Nitrocellulose

THE course of the thermal breakdown of the nitrocellulose molecule is not well understood. Previous studies of the chemical kinetics of the reaction have been carried out on the solid, and so have been hampered by the need to pyrolyse at low temperatures to reduce self-heating; and it is not certain how far the kinetics of gas evolution are complicated by reactions of the primary products, which probably include nitrogen peroxide. Further, the value of 46·7 kcal./mole recently found for the activation energy of the primary step by Wilfong, Penner and Daniells[1] is difficult to understand in the light of Phillips's demonstration[2] that the typical value for organic nitrates is 36–40 kcal.

A fresh experimental approach to the problem is suggested by Robertson's work on the pyrolysis of solutions of pentaerythritol tetranitrate[3] and cyclotrimethylenetrinitramine[4]. If nitrocellulose also could be studied in dilute solution, the difficulties we have mentioned would be much reduced. We have, in fact, found three solvents for nitrocellulose permitting such a study to be made, which have in sufficient degree the necessary qualities of chemical inertness towards nitrocellulose, low vapour pressure, and low melting point. They are 1-chloro-2 : 4-dinitrobenzene, benzophenone and 1-nitronaphthalene.

A preliminary study of the pyrolysis of nitrocellulose in these solvents between 165° C. and 200° C. has been made by following the evolution of gas, usually from 1 gm. of a 1 per cent solution of the *HX* 30/50 grade of nitrocellulose (11·85 per cent nitrogen). The usual assumption that the reaction is of the first order has proved to be approximately true; but there are certain deviations from the first-order law, as is not surprising in a reactant of this complexity. Thus, during the first one-third of the reaction in 1-chloro-2 : 4-dinitrobenzene, the rate of evolution of gas shows only a slight fall, corresponding to a gradual increase of about 25 per cent in the rate constant; whereas during the last quarter, the rate constant falls to about 60 per cent of its value at the intermediate stage. If one specifies the rate of the reaction, perhaps rather arbitrarily, by the velocity constant prevailing over the middle of its course, one finds that the rates at 175° C. in the three solvents show a spread of only 20 per cent, a sufficiently close agreement to suggest that the solvents are inert towards nitrocellulose.

In 1-chloro-2 : 4-dinitrobenzene, the rates at six temperatures between 165° C. and 200° C. lead to the following equation for the velocity constant :

$$k(\text{sec.}^{-1}) = 10^{18\cdot 6} \exp\,(-43\cdot 0 \times 10^{3}/RT).$$

The average deviation, without regard to sign, between the observed rates and those calculated from this equation is 7 per cent. It is unlikely that this preliminary value of 43·0 kcal. for the activation energy is in error by more than 2 kcal. It is therefore doubtful whether nitrocellulose is behaving as a normal nitrate when judged by Phillips's criterion of the activation energy. The reason for the high value of $10^{18\cdot 6}$ for the B factor is not certain, but even higher values have been recorded before, and Wilfong, Penner and Daniells probably seriously under-estimate the rate of decomposition in this temperature-region when they assume in effect that B has its 'normal' value of 10^{13}.

In 1-chloro-2 : 4-dinitrobenzene and benzophenone solutions, about five molecules of gas come from each sub-molecule of nitrocellulose. This yield of gas seems at first sight small, but it has been observed before[5] that much, perhaps one-half, of the products of pyrolysis of nitrocellulose is involatile. From 1-nitronaphthalene solutions, however, the yield is only 3·5 molecules per sub-molecule. Here the solvent presumably absorbs some of the products, but this need not invalidate the rates measured for its solutions. The reaction products have not been analysed.

Paper Chromatographic Separation of Barbituric Acids

THE barbituric acid derivatives have a characteristic absorption spectrum in the ultra-violet, and this is the basis of the most reliable methods for their quantitative determination. Small changes of the wave-length at which maximal absorption is found and changes in the absorption curve with varying pH usually are considered to be the means by which the different members of the group can be identified. But these methods have been found troublesome and unreliable. However, as the strength of absorption differs quite appreciably from one member to another, the identification of the derivative is necessary for a quantitative determination.

It seemed theoretically that paper chromatography might be a method for separation and identification, but a difficulty was the lack of any means of detection of the spots. Several colour reactions found in the literature were tried, but were not found reliable. It was clear that a new method had to be worked out, and the following procedure was found to give good results with most derivatives tested.

After development, the dried paper is sprayed with $N/2$ sodium hydroxide, and dried again. It is then brought in firm contact with a fluorescent screen and placed in front of an ultra-violet lamp, the paper facing the light. A low-pressure mercury lamp with a suitable filter letting through a fairly monochromatic light of about 2537 A. and a screen which fluoresces in this light have been used. The acids are seen as dark spots on the fluorescent screen. The method proved to be very sensitive.

As the absorption of the barbiturates is highest at a pH between 9 and 10, the spraying of the paper with an alkaline solution is very important. The resultant alkalinity of the paper is not known, and experiments are in progress to investigate which alkaline solution is to be preferred.

This arrangement of a screen which fluoresces with ultra-violet light seems to be a sensitive method for the detection of all kinds of substances absorbing ultra-violet light, and probably it has wide applications. Permanent records can, of course, be made in the usual way, by taking photographic contact prints of the sprayed and dried paper. It is, however, more convenient to draw pencil marks around the spots on the paper. After copying the drawing, the spots can be extracted if desired. By using this method it was found that the different barbituric acids could be separated by paper chromatography.

We are continuing to investigate this method and a full account will appear in the near future.

Specificity of Vitamin B_{12} for *Euglena*

IN an earlier publication[1] we reported that vitamin B_{12} could not be replaced for *Euglena gracilis* var. *bacillaris* by vitamin-free casein hydrolysate, carbon-treated peptone, methionine, ascorbic acid, pteroylglutamic acid, a variety of purine and pyrimidine bases or by xanthopterin and a number of related compounds. Hutner *et al.*[2] found thymidine to be ineffective. Vitamin B_{12a} (hydroxocobalamin) was active[1]. We have examined a number of additional compounds for vitamin B_{12} activity on *Euglena*.

Emerson *et al.*[3] reported the vitamin B_{12}-like activity of α- and β-ribazole and some related compounds. Samples of these compounds were obtained through the courtesy of Dr. Karl Folkers and tested on *Euglena* in our liquid medium I [1,4]. At 0·166 mgm. per ml., α- and β-ribazole had an activity on *Euglena* equivalent to 1–3·4 μμgm. of vitamin B_{12} per ml. At 0·00166 mgm. and 0·0000166 mgm. per ml. no effect was observed. For *Euglena*, vitamin B_{12} was from 50,000,000 to 150,000,000 times as active as α- or β-ribazole; for rats, Emerson *et al.* found vitamin B_{12} to be 400 times as active as the ribazoles. At 0·166 mgm. per ml., 1-D-ribityl-5,6-dimethylbenzimidazole and 5,6-dimethylbenzimidazole were inactive on *Euglena* in our experiments. Emerson *et al.* found vitamin B_{12} to have from 8,000 to 20,000 times the activity of the two benzimidazoles on rats. Although the results with *Euglena* agree with those on rats, in that the α- and β-ribazoles were more active than the two benzimidazoles, all the compounds were much less effective than on the rat.

Woolley[5] found that 1,2-dimethyl-4,5-diaminobenzene increased the synthesis of vitamin B_{12} by *Bacillus megatherium*, whereas 1,2-dichloro-4,5-diaminobenzene reduced its synthesis and in sufficient amounts inhibited growth. He suggested that the former compound might be a precursor for vitamin B_{12} and the latter an antagonizer of the precursor. Dr. Woolley generously supplied us with some of each of the above compounds. At 0·5 mgm. per ml. in our liquid medium I, the dichloro compound had little or no effect on the growth of *Euglena* in the presence of 0·00002 μgm. of vitamin B_{12} per ml. Woolley found 0·1 mgm. per ml. under his conditions reduced growth of *Euglena* by 50 per cent. In our experiments the dimethyl compound at 0·1 μgm. per ml. in the absence of vitamin B_{12} had no effect on the growth of *Euglena*. Since *Euglena* responds under our conditions to 1 μμgm. of vitamin B_{12} per ml., the dimethyl compound had less than 1/100,000 the effect of vitamin B_{12}. Woolley reported 1,2-dimethyl-4,5-diaminobenzene to be between 1/500,000 and 1/1,000,000 as effective as vitamin B_{12} for *Euglena gracilis*.

Through the courtesy of Dr. T. H. Jukes, a sample of ammonia cobalichrome was obtained from Dr. V. Petrow (his *AC2*). This compound is vitamin B_{12} with ammonia substituted for cyanide. We were advised that the substance was unstable and could not be heated for long periods in the light. We sterilized a solution of the compound by filtration and pasteurized an aliquot by bringing it to a quick boil. With both methods the substance was added to our liquid medium I after the latter had been sterilized, and the cultures were incubated in the dark at 25° C. Both the filtered and pasteurized samples of the ammonia cobalichrome had about one-half the activity of vitamin B_{12}. According to Cooley *et al.*[6], ammonia cobalichrome has 2·5 times the activity of vitamin B_{12} for *Lactobacillus lactis*, 1·5 times its activity for *Escherichia coli* and equal activity for the chick.

Pfiffner *et al.*[7] reported the isolation of an organism from bovine rumen which under anaerobic conditions produced a mixture of cobalt-containing pigments belonging to the vitamin B_{12} group. Two major constituents were obtained in crystalline form. They had the same order of activity on *L. leichmannii* and *L. lactis* Dorner as vitamin B_{12} but were inactive on chick growth and rat anti-hæmorrhagic kidney tests. Dr. Pfiffner kindly supplied us with samples of crystalline pseudovitamin B_{12}[8], crystalline pseudovitamin B_{12b} and cyano-pigment *C*. Pseudovitamin B_{12} is about as active on *L. leichmannii* and *L. lactis* as vitamin B_{12}; pseudovitamin B_{12} has about half the activity of B_{12} on *L. leichmannii*, *L. acidophilus* and *L. lactis* Dorner, and cyano-pigment *C* has only a trace of activity on *L. leichmannii*[9]. Pseudovitamin B_{12} and pseudovitamin B_{12b} had the same order of activity on *Euglena* as vitamin B_{12}. The activity of cyano-pigment *C* was about half that of vitamin B_{12}.

Dr. C. A. Elvehjem furnished us with a preparation of a substance containing cobalt[10] which was isolated from rat fæces. The material was active on *L. leichmannii* and the chick, but had little or no activity for the rat. In our hands this material had about twice the activity for *E. gracilis* as reported for *L. leichmannii*.

Although vitamin B_{12} has a high degree of specificity for *Euglena gracilis* var. *bacillaris*, our results demonstrate that substances exist in Nature which have vitamin B_{12} activity for *Euglena* and little or none for animals. Assays for vitamin B_{12} made with *Euglena* are not sure indications of the presence of the vitamin.

This investigation was supported in part by the Lucy Benjamin Rogers Fund and the Howard Bayne Research Fund of the New York Botanical Garden.

Nucleic Acids of Rickettsiæ

Smith and Stoker[1] have noted that the deoxyribonucleic acid of *Q*-fever rickettsiæ (*R. burneti*) grown in embryonated eggs is closely similar in composition to that of chick embryos, the only significant difference being lack of 5-methyl cytosine from the former. To account for this similarity, they mention the possibility that rickettsiæ may incorporate nucleic acid directly from their host. This hypothesis could be tested, they point out, by analysis of the same organism grown in a different host.

We have recently analysed the deoxyribonucleic acid of another rickettsia from the same host. Deoxyribonucleic acid was isolated[2] from epidemic typhus rickettsiæ (*R. prowazeki*) grown in chick yolk-sac endothelium, and the purine and pyrimidine bases estimated[3] after hydrolysis in perchloric acid (70 per cent, 1 hr. at 100° C.). The estimated bases were equivalent to 96 per cent of the deoxyribonucleic acid phosphorus. No methyl cytosine could be detected. The ratios of the bases found (mean of two analyses), along with those reported for *R. burneti*, are as follows:

	Moles per cent			
	Adenine	Thymine	Guanine	Cytosine
R. burneti (ref. 1)	29·5	26·0	22·5	22·0
R. prowazeki	35·7	31·8	17·1	15·4

The deoxyribonucleic acid of *R. prowazeki* clearly differs in composition from those of *R. burneti* and of the host chick embryos. In the *E. coli*-phage system, the deoxyribonucleic acids of host and virus differ markedly[4], and it has been concluded from tracer studies[5] that host nucleic acid is utilized by the parasite only in the form of breakdown products. It is likely that any host nucleic acid used in synthesis of rickettsiæ would also be first extensively degraded.

A common pattern in the composition of deoxyribonucleic acid, first pointed out by Chargaff[6], has apparently wide validity. The molar ratios (adenine) : (thymine), and (guanine) : (cytosine (plus methyl cytosine when present)) have nearly constant values close to unity, whereas the ratio (adenine + thymine) : (guanine + cytosine) is characteristic of the source of the nucleic acid. The rickettsiæ are no exception :

	A/T	G/C	(A + T)/(G + C)
R. burneti	1·13	1·02	1·25
R. prowazeki	1·12	1·11	2·08

If, for as yet obscure reasons, nearly constant ratios of adenine to thymine and guanine to cytosine are the rule in deoxyribonucleic acids, this would greatly increase the probability of two distinct deoxyribonucleic acids having like composition by chance. This may account for the similarity of the *R. burneti* and chick nucleic acids.

Symbiosis in *Ptilinus pectinicornis* L.

It is well known from the work of Buchner[1], Breitsprecher[2], and others that mycetomes occur at he anterior end of the larval midgut of several species of Anobiid beetles. The mycetocytes are distended with micro-organisms which are of obscure axonomy, but appear yeast-like, and of which the ymbiotic role has been established by Koch's[3] demonstration of their necessary presence in *Sitodrepa anicea*, if the larva is to grow normally. Blewett and Fraenkel[4] have shown that the presence of the ymbionts in *Sitodrepa* larvæ can offset a dietary deficiency of five vitamins of the B group: the ymbionts in *Lasioderma serricorne* can apparently supply six of these vitamins to the larva.

The vitamins could become available to the larva ther by excretion from the organisms, or by digestion of organisms expelled from the mycetocytes into the gut. The former view now gains support om the observation that, in the larva of *Ptilinus ectinicornis*, the mycetomes have migrated forward from the anterior end of the midgut to form a pair of lobed organs dorso-lateral to the front of the gizzard. Connexion with the midgut is retained through a pair of slender ducts, about 16 μ in external diameter, with walls about 4 μ in thickness, passing on either side of the gizzard. These organs are observable both in sections and in dissections. In sections, the mycetocytes can be seen to be packed with minute, round organisms, none of which has been observed in the ducts.

There is therefore strong morphological evidence for concluding that the symbionts in the larva of *P. pectinicornis* secrete a fluid which, by analogy with *Sitodrepa* and *Lasioderma*, should contain vitamins of the B group which the larva requires but is unable to obtain in sufficient quantities from the dead, dry wood in which it normally lives.

When the larva pupates, the mycetomes retain their identity but become a little reduced in size, while the ducts contract and thicken until the mycetomes are drawn back into close contact with the anterior end of the midgut. The mycetomes then look little different from those in the larvæ of several other species of Anobiids in which they appear as short diverticula from the midgut.

Occurrence of Malonic Acid in Plants

The occurrence of malonic acid has been reported in the leaves of lucerne[1] and in green wheat plants[2]. This acid is well known as a competitive inhibitor of succinic dehydrogenase, and has been used extensively in investigations of the tricarboxylic acid cycle. In consideration of this inhibiting effect of the acid, some further investigations have been made into its presence in plants.

The organic acids present in water extracts of plant tissue have been identified and quantitatively estimated by paper partition chromatography. The acids were extracted from mature leaves by boiling about 6 gm. in water with 1 ml. normal sulphuric acid. The tissue was then ground in a mortar and a clear extract obtained by centrifuging; this was concentrated to 6 ml. before using on the chromatogram. The chromatograms were developed by a method similar to that of Lugg and Overell[3], using as solvent the water-poor phase of *tert.*-amyl alcohol (80 ml.) – chloroform (80 ml.) – water (80 ml.) – formic acid (30 ml.). The acids were detected by spraying with an aqueous solution of bromocresol green. The R_F value of malonic acid (0·59) is identical with that of tricarballylic acid and very close to that of maleic acid (0·60). Malonic acid was distinguished from the others by the use of two different sprays—ammoniacal silver nitrate and ceric ammonium nitrate as suggested by Buch *et al.*[4]. The organic acids separated satisfactorily in the presence of the other substances, for example, amino-acids and sugars in the plant extracts. An acid was only identifiable with this technique when more than 15 μgm. were present on the chromatogram, therefore acids present in a concentration below 0·5 mgm./ml. of extract, that is, 0·5 mgm./gm. fresh weight of tissue, were not identified in this type of extract.

Mature leaves from twenty-seven species of Leguminosæ were examined. Citric and malic acids were present in all of them in concentrations of 1·0–4·0 mgm./gm. fresh weight. Malonic acid was present in concentrations of 0·5–2·0 mgm./gm. fresh weight in eighteen species taken from the genera *Medicago*, *Phaseolus*, *Vicia*, *Ononis*, *Astragalus*, *Trifolium*, *Lupinus*, *Anthyllis*, *Lotus*, *Melilotus*, *Colutea*, *Sophora*, *Thermopsis* and *Trigonella*. Malonic acid could not be identified in nine species taken from the genera *Lathyrus*, *Onobrichis*, *Vicia*, *Cercis*, *Mimosa*, *Piptanthus*, *Hedysarum*, *Cassia* and *Gleditschia*. Other species examined included members of the Umbelliferæ, Rosaceæ, Ranunculaceæ, Chenopodiaceæ and Crassulaceæ. Of these only the Umbelliferæ showed an accumulation of malonic acid comparable to that in the Leguminosæ; for example, the leaves of *Anthriscus* and *Apium* contained more than 1·0 mgm./gm. fresh weight. As well as the accumulation of malonic acid found frequently in these two families, it seems probable that it occurs in smaller concentrations elsewhere. For example, extracts of the leaves of *Helianthus annuus* L., purified and concentrated by the use of ion-exchange resins, were found to contain citric and malic acids (1·0 mgm./gm. fresh weight) and much smaller quantities of malonic, lactic, succinic, aconitic and fumaric acids.

Confirmation of the identification of malonic acid in the leaves of runner bean, *Phaseolus coccineus* L., has been provided by isolation of the pure acid. A water extract of the leaves was purified and concentrated on ion-exchange resins. The acids were separated by paper chromatography, and citric, malic, malonic, lactic, succinic, aconitic and fumaric acids were identified. A chromatogram was run with a complete band of extract along the starting line; after separation the band of paper corresponding to malonic acid (calculated to contain 60 mgm.) was excised and the acid extracted from it with boiling water. On recovery from the water and recrystallization from ethyl acetate, 20 mgm. of crystals were obtained, m.p. 131–133° C. (m.p. malonic acid = 135° C.); there was no depression of the mixed melting point. The *p*-nitrobenzyl ester of the plant acid melted at 83·5–85° C. (m.p. malonic acid ester = 86° C.) and there was no depression of the mixed melting point.

Analysis of the stem tissue of runner bean gave in mgm./gm. fresh weight, citric acid = 0·7, malic acid = 1·1, malonic acid = 2·1 and succinic acid = 0·15. It is therefore necessary in investigations into the reactions of the tricarboxylic acid cycle in such tissues to take into consideration the presence of endogenous malonic acid. For example, the malonic acid forms a solution about 0·03 M in the expressed sap of runner bean stem, and it has been found that a solution as low as 0·02 M malonic acid, adjusted to pH 4·5 with caustic potash, inhibits by 50 per cent the oxygen uptake of disks of this tissue and causes accumulation of succinic acid. Further investigations into the acid metabolism of this tissue are being carried out and full details will be published later.

I wish to thank Prof. T. A. Bennet-Clark for his advice and encouragement during the course of this work and Mr. R. D. Mulley, of the Chemistry Department of King's College, for preparation of the ester of malonic acid.

Variation in Leaf Form in *Callitriche Intermedia*

Callitriche intermedia shows a well-marked variation in its leaf form, dependent on whether the crown of the plant is submerged or floating at the surface of the water. When the crown is submerged, linear leaves are produced, up to 3 cm. in length and 1 mm. broad. When the crown reaches the surface, ovate leaves are produced, about 1·5 cm. long and 4 mm. broad at the widest point. A reversion to the linear type of leaf is produced if the crown is afterwards submerged.

In considering the mechanism involved in the change in leaf form, it is of interest to refer to the work of McCallum[1] on *Proserpinaca palustris*, where an essentially similar response of leaf form to emergence from the water was studied. McCallum was able to induce the aerial type of leaf by growing the plants in a nutrient solution of a concentration which just failed to plasmolyse the tissues. No compensation for evaporation from the nutrient solutions was made. The suggestion was advanced that the withdrawal of water from the tissues by osmosis created an effect similar to the withdrawal of water by transpiration on exposure to the air. Burns[2], in a criticism of McCallum's work, stated that the aerial type of leaf was produced in the spring and was formed even on submerged shoots at that season. Burns suggested that light was the determining factor in the production of the aerial leaf form.

I have applied a modification of McCallum' methods to *Callitriche intermedia*. Linear-leave shoots were submerged in sea water diluted to 30 pe cent of its original concentration (30 per cent se water just fails to plasmolyse tissues of the linea leaves). In seventeen days (July) small, ovate leave were visible at the crowns. These ovate leaves wer preceded by transitional forms, the intermediat leaves having a more or less ovate proximal part an a linear distal part. The concentration of the dilute sea water was now about 37 per cent. Ovate-leave shoots grown under the same conditions remaine ovate-leaved. Linear-leaved shoots submerged i tap-water remained linear-leaved, while ovate-leave shoots submerged in tap-water produced linear leave

The ovate leaves which are produced by immersio in diluted sea water have the general form of th normal ovate leaves but do not attain a length more than 3 mm. The induced leaves resemb normal ovate leaves in the possession of numero stomates and of isodiametric epidermal cells. Norm linear leaves have few or no stomates, and th epidermal cells are elongated in the direction of th length of the leaf. The induced ovate leaves, howeve have a single vein as in the linear leaf, whereas th normal ovate leaf has three veins. An interestir feature of the shoots bearing induced ovate leaves is the development of axillary buds (with ovate leaves) associated with the absence of elongation of the shoot after immersion in the diluted sea water.

These results are being considered in relation to a general study of heterophylly in *Callitriche intermedia*.

Lowered Liver Vitamin A Reserves in Avian Coccidiosis

DURING the course of a routine series of determinations of vitamin A reserves of poultry in health and disease it became evident that, in the case of fowls affected with coccidiosis, these reserves were almost invariably of a low order.

The range in a series of thirty-nine affected birds submitted for diagnosis from farms in different parts of England was 0–126 I.U. vitamin A/gm., with a mean value of 6·9 I.U./gm.

The birds in question were of varying ages and breeds and were from farms on which widely different systems of husbandry were practised. The infections included both the cæcal type (*Eimeria tenella*) and the intestinal type (*Eimeria necatrix*) of coccidiosis.

Observations were therefore extended to a series of ten Barred Rock and Brown Leghorn × Barred Rock fowls which were suffering from a natural infection of intestinal coccidiosis, and which were from a flock maintained at the Poultry Research Station of the Animal Health Trust, where they had been reared on range in fold units. The ages of the birds varied from 8 to 24 weeks, but in all cases the liver vitamin A reserves were again of low order, the range being 2–38 I.U./gm. with the mean of 20·8 I.U./gm. The food provided was a nutritionally balanced ration and was known to contain 2,100 μgm. carotene = 3,500 I.U. vitamin A/lb. in the form of dried grass meal. The livers of ten unaffected birds from the same flock were examined and found to have normal reserves within the range of 200–420 I.U./gm., with a mean value of 292 I.U./gm.

These findings would appear to be of special interest in view of the fact that the intestine is now recognized as the seat of conversion of carotene to vitamin A, in chicks as well as mammals[1]. It is suggested that invasion of the intestinal wall by the coccidia may have resulted in impaired conversion of carotene to vitamin A. Moreover, it has been shown that the provision of adequate amounts of cod liver oil accelerates recovery from coccidiosis[2], and this may be due to its vitamin A content.

These studies are now being extended to birds artificially infected with *Eimeria necatrix* and receiving vitamin A either as the vitamin A alcohol or as carotene.

I am grateful to Dr. Horton-Smith for his collabration.

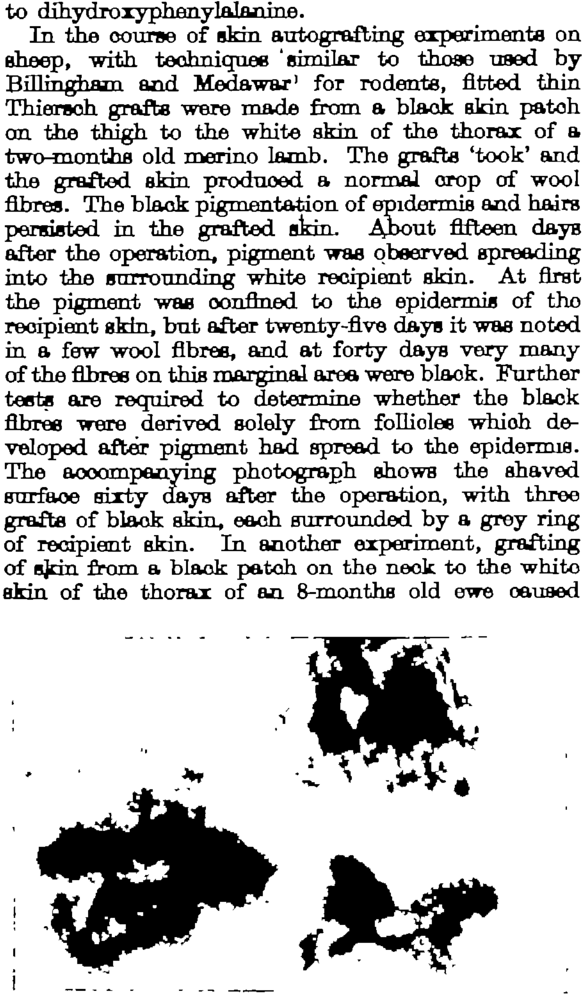
Spread of Pigment in Sheep Skin Autografts

SEVERAL theories have been advanced to explain the spreading of melanin pigmentation in mammalian skin during post-natal life[1]. Billingham and Medawar[2] found support for their theory of 'infective' cellular transformation from skin grafting experiments with guinea pigs. It is well known that if black skin from an adult guinea pig is grafted on to a white area on the same animal, melanin pigment appears in the white skin surrounding the graft, though not in the hairs. A similar phenomenon was recently observed with grafts of cattle skin[3]. The spreading of pigment to surrounding hairs instead of to epidermis has been reported in homografts to new-born mice[4] and in autografts to new-born black hooded rats[1]; but, so far as we are aware, it has not been observed in the healthy skin of more mature mice or rats, nor in any species other than the above.

In the black skin of sheep, pigmented dendritic cells are present in the hair matrix of hair follicles and in varying concentrations in the root sheaths and the basal layer of the epidermis. Boyd[5] showed that dihydroxyphenylalanine-positive but unpigmented dendritic cells were present in the same locations in the white skin of spotted and recessive white breeds. The distribution of dendritic cells was the same in spotted guinea pigs[2], although in the latter the unpigmented dendritic cells were negative to dihydroxyphenylalanine.

In the course of skin autografting experiments on sheep, with techniques similar to those used by Billingham and Medawar[1] for rodents, fitted thin Thiersch grafts were made from a black skin patch on the thigh to the white skin of the thorax of a two-months old merino lamb. The grafts 'took' and the grafted skin produced a normal crop of wool fibres. The black pigmentation of epidermis and hairs persisted in the grafted skin. About fifteen days after the operation, pigment was observed spreading into the surrounding white recipient skin. At first the pigment was confined to the epidermis of the recipient skin, but after twenty-five days it was noted in a few wool fibres, and at forty days very many of the fibres on this marginal area were black. Further tests are required to determine whether the black fibres were derived solely from follicles which developed after pigment had spread to the epidermis. The accompanying photograph shows the shaved surface sixty days after the operation, with three grafts of black skin, each surrounded by a grey ring of recipient skin. In another experiment, grafting of skin from a black patch on the neck to the white skin of the thorax of an 8-months old ewe caused



spread of pigment into the recipient epidermis, but there was little or no pigmentation of recipient hairs.

These observations were confirmed by the histological study of skin samples taken at frequent intervals. In normally black skin, pigmented dendritic cells were found in the basal layer of the epidermis and in the outer root-sheath and hair matrix, and melanin granules were found in some epidermal cells and in the cortex of most hairs. This distribution of pigment persisted in black skin after it was grafted to a white area, and, after twenty to thirty days, pigmented dendritic cells appeared for the first time in the adjacent recipient area, first in the basal layer of the epidermis and later in a few follicles, in the hair matrix or the outer root sheath.

The behaviour of black-on-white skin autografts in the sheep was very similar to that in adult guinea pigs[3] and cattle[4]. In both guinea pigs and sheep, pigmented dendritic cells appeared in the surrounding host epidermis; in both, this might be due to the transformation of the white dendritic cells already present. Pigmentation of follicles and hairs in the host skin occurred to some extent in the sheep but not in the guinea pig or the cow. In all three species the spread of pigment began twenty to thirty days after the grafting operation and the rate was about 1 mm. per week for several weeks.

The sheep thus appears to be a useful subject for the study of the nature of pigment spreading. Further experiments are in progress and will be reported in detail elsewhere.

A Lipoprotein Precursor of Sclerotin in the Cockroach Cuticle

RECENT work has shown that quinone tanning of protein structures is indeed of widespread occurrence in the invertebrates, as was suggested by Dennell[1]. The various tanned structures agree in showing a high degree of chemical stability, but the origin of the quinone responsible for tanning has been claimed to differ in different cases[2]. On one hand, in the cockroach ootheca[3] and in the blowfly puparium[4], the quinone has been shown to arise from the enzymatic oxidation of an alcohol-soluble dihydroxyphenol. In certain structures of *Mytilus* and in the egg cases of *Fasciola*[2], on the other hand, it has been suggested that the precursor of the quinone is an alcohol-insoluble amino-acid or protein in which tanning may have evolved through the oxidation of the phenolic hydroxyl groups of tyrosine without removal of the side-chains. A protein, 'prosclerotin', rich in phenolic groups has likewise been described in the cuticle of Myriapods[5], and it has been suggested that this may constitute a similar self-tanning substance.

In the present work, the process of hardening c the cockroach cuticle has been critically followe histochemically and by microchemical analysis, an two conclusions of importance emerge. First, th precursor of sclerotin, the impregnating material c the exocuticle, has been clearly shown to be a lip protein complex similar to that suggested by Wiggle worth[6] as constituting the cuticulin of the epicuticl Secondly, the quinone responsible for the tannin of this precursor is derived from the oxidation of dihydroxyphenol in the presence of a polyphen oxidase at the surface of the cuticle. Hitherto, it h not been unequivocally shown that the hardenin of the exoskeleton of a typical insect takes place i the same manner as in the special cases of the cocl roach ootheca[3] and the blowfly puparium[4].

Sections of the fully hardened cuticle show th tanning involved only the outer zone of the soft pr exuvial endocuticle of the sclerites, whereas the re of the cuticle, as well as the whole of the arthrodi membranes, remains untanned. During preparatic for hardening, a lipoid passes into the presumpti exocuticle, and is shortly followed by a protein ri in phenolic groups which comes to occupy the sam region as the lipoid. The lipoid, shown by th Liebermann–Burchardt test to be a sterol, impar a yellow coloration to the cuticle. The protein sho many of the properties of the 'prosclerotin' of Blowe except that it is restricted to the regions later be tanned, whereas 'prosclerotin' is reported to present throughout the thickness of the sclerite. the two constituents, lipoid and protein, only t latter reduces ammoniacal silver nitrate, and th only to a slight extent. It is likely that the stabili shown by the exocuticle at this stage is due to t presence of the lipoid constituent. Just before t onset of darkening the lipoid loses its colour a ability to stain, possibly as a result of polymerizatic A wave of quinone tanning demonstrable by a pr nounced intensification of the argentaffin reacti then passes from the epicuticle inwards and sto sharply at the inner boundary of the lipoprote complex.

That the inward spread of darkening is truly d to the passage into the cuticle of a dihydroxyphe and its subsequent oxidation to an *o*-quinone, a is not the result of the presence of a self-tanni protein, is indicated by the results of micro-analys which show clearly the presence of dihydroxyphen in the cuticle during the later stages of the proce Further than this, the blood at all stages of hardeni darkens on exposure to air, indicating the presen in it of tyrosine and tyrosinase, and in the later sta there is evidence of the presence of a free phen Finally, the epicuticle of the sclerites, but not of t arthrodial membranes, contains a polyphenol oxid readily demonstrable by the 'Nadi' reagent. Th observations are in fundamental agreement with th of Dennell[4] on *Sarcophaga*.

It appears, then, that the substance tanned i lipoprotein complex, and not the structural prot of the procuticle[4], nor a simple protein passed preparatory to hardening[5]. Experiments on the a ficial tanning of cuticles before the onset of natural process indicate that not only does quinone combine with the lipoprotein complex in natural hardening, but also with the sterol al at an earlier stage. It is suggested that it such a sterol-protein complex, the precursor sclerotin, that has been designated prosclerotin Blower[5].

A lipoprotein complex may be of common occurrence in naturally tanned structures. In both the cockroach ootheca and in the blowfly puparium, I have clearly demonstrated a lipoid to be present throughout the whole thickness of the tanned regions. Furthermore, lipoids have been reported in the exocuticle of Myriapods[7]. It will be of interest to learn whether lipoids are associated with proteins in other tanned structures.

A full account of this and other aspects of the present work will be given elsewhere. My thanks are due to Prof. R. Dennell for his interest and criticism.

Packed Red-Cell Volume in the Tropics

It was found that when men stayed in air-conditioned rooms at about 30° C. for a few days their packed red-cell volume fell[1,2]. A rise in this value was likewise found in conditions of low environmental temperature[2]. More prolonged exposure to conditions of high environmental temperature caused by change of season was also associated with a fall in the packed red-cell volume[3]. No satisfactory information about the physiological effect on the packed red-cell volume of people living for several months or years in a warm climate could be found in the available literature. The results of an investigation made in Singapore may, therefore, be of interest.

The subjects were healthy, well-nourished men and women of different races (see table) who had lived in the tropics for at least six months, and they were all between twenty and forty years old. Samples of venous blood were collected with minimal stasis, and an ammonium and potassium oxalate mixture used as an anti-coagulant[4]. Estimations of the packed red-cell volume were made by means of Wintrobe haematocrit tubes[5] which were centrifuged for 1 hr. at 3,000 r.p.m.

Packed Red-Cell Volume of Normal Men and Women Living in Singapore

Racial group	No.	Mean (per cent)	S.D.	S.E. of mean
Men				
Chinese	73	47·69	6·518	0·7622
Indians and others	58	47·59	7·266	0·9541
European	121	47·02	5·420	0·4927
All males	252	47·35	4 508	0·2838
Women				
Europeans	57	40·56	6·060	0·8025
Asians	21	41·48	9·824	2·1440
All females	78	40 80	5·429	0·6146

The mean packed red-cell volume of 252 men was 7·35 per cent, and that of 78 women 40·80 per cent. Details are given in the table. The differences between he mean value for each racial group were not tatistically significant by the *t* test[6].

The present findings are slightly higher than those found in temperate climates[7]. The results of this investigation suggest that living in a warm environment for several months or years is not associated with a fall in the packed red-cell volume. The fall in this value found in men during shorter conditions of exposure to heat[1-3] appears to have been a temporary change. Recovery of the packed red-cell volume might provide objective evidence of complete acclimatization.

Reversal of the Heart-beat in Tunicates

The mechanism controlling the periodic reversal of the heart-beat in tunicates is still in dispute. Internal control has been thought to exist, and to be due either to local nerve centres[1], or to physiologically differentiated areas of cardiac muscle[2], at each end of the heart. Evidence from the action of drugs has been conflicting[3]. Hunter[1] found a ring of cells around each end of the heart which he thought to be nerve cells, and Alexandrowicz[4] described nerve fibres but was uncertain whether ganglion cells exist.

I have found rings of fusiform cells in the heart of *Ciona intestinalis* (L) which seem to correspond to those described by Hunter[1], but they are connective tissue cells and not nerve cells, being the ends of sheets of connective tissue that line the large blood vessels at their cardiac junction. Von Skramlik[2] found evidence for the existence at each end of the heart of a small area of cardiac muscle which initiates the beats; alternating dominance of one area over the other would produce periodic reversal. Lahille[5] believed that certain parts of the peripheral system are unable to accept blood as quickly as the heart supplies it, and that the resulting back-pressure that is built up eventually stops the heart. When the heart starts to beat again, it does so in the opposite direction. Haywood and Moon[6] have revived Lahille's theory and from it have formulated an equation relating the time of beating in one direction with the number of beats. In support of the theory they produced experimental results which satisfied the equation, and also they failed to observe reversal of isolated hearts, a phenomenon recorded by von Skramlik[2].

Periodic reversal of isolated hearts, if it could be shown to occur, would be strong evidence against the back-pressure theory, since no such pressure can be built up in a heart not connected with its closed system of vessels. The heart was therefore removed from a number of specimens of *Ciona* and observed continuously for 6–12 hr. It was found that, in most cases, the newly isolated heart continued to beat in one direction during the first few hours, but eventually reversal started, at first at long intervals but with increasing frequency. The duration, in minutes, of alternate phases in two typical isolated hearts is given, both series being taken about eight hours after isolation. The figures in italic type are for the abvisceral phase, and those in roman type for the advisceral phase.

Specimen 1. *5* 6 *2* 2 *4* 3 *4* 3 *3½* 3 *3* 3½ *1½* 3 *4½* 3½ *3* 3½ *4*
Specimen 2. *1½* 6 *6* 18 *5* 16 *3* 14 *5* 10½ *5* 12 *1½* 14 *12½* 18½ *12* 8 *4½* 10½ *7*

In some of the preparations the wall of the heart was cut open to ensure that the pressures of liquid inside and outside were equal; in others the ends sealed themselves so that a constant pressure was maintained within the heart. In each kind of preparation periodic reversals were made.

The sequence of events during reversal of a weak and slowly beating isolated heart also shows that it is not back-pressure which stops the heart. There is a distinct pause between beats, and very little movement of liquid is produced. Nevertheless, such hearts still reverse, and it can be seen that, immediately before reversal, the hitherto quiescent end starts to beat in opposition to the dominant end, but only takes over control from the latter when, owing to its increasing rate of beat, it initiates a beat before the hitherto dominant end.

I conclude from these experiments that the back-pressure theory is untenable, and that there exists some internal controlling mechanism of the kind described by von Skramlik[2]. Periodic pressure changes may, of course, influence the behaviour of the heart in the intact animal, and may have some effect on the periodicity of reversal; but any such effect is superimposed on the pattern of reversal inherent in the heart.

Level of National Intelligence

THE results of the Scottish Mental Survey[1] presented a paradox which has been difficult to resolve. These results showed a small rise in mean intelligence test score in the eleven-year-old population over a period of fifteen years; but they also established the existence of a negative correlation between intelligence test score and family size—a tendency for intelligent children to be found in small families—which implies the danger of a possible decline in national intelligence, in so far as intelligence is inherited. Though the existence of this negative correlation has now been established, its cause is the subject of considerable controversy, and predictions of the future level of national intelligence depend on how far it can be attributed to a limiting of families by intelligent parents or to the depressive effect of a poor environment on the test scores of children from large families.

The former cause is suggested by the results of previous investigations in which attempts to hold constant such factors as parental occupation or overcrowding in the home have failed to dispel the negative correlation; but such methods are not adequate if the actual size of family is itself an environmental factor—if the lack of adult contact and consequent retardation in verbal development suffered by a child from a large family depress the environmental component of his test score. Such a hypothesis has been shown to be tenable in a survey I have carried out of some 7,600 Aberdeen children; it is consistent with findings in other fields, for example, in the comparison of orphanage children and only children, in studies of bilinguals, deaf children and twins; and model populations can be constructed to show how, on such a hypothesis, the paradox of the Mental Survey results may be resolved, the observed rise being due to improved conditions or to a greater proportion of small families.

While the practice of previous investigators has been to apply one intelligence test to as large a group of children as possible, the method I followed in the Aberdeen survey was to apply several tests with different verbal loadings to the same children. In two groups each of some 2,500 children, aged eleven the partial correlation between size of family and score in a test of English attainment (with intelligence test score held constant) was negative (about − 0·1) and significant in both groups at the 0·05 level. In a random sample of two hundred children aged eleven, the correlation between size of family and score in the non-verbal Matrices Test was − 0·20 while the correlation between size of family and score in a verbal Moray House Test was − 0·30, the difference being significant at the 0·05 level.

These results support the hypothesis that the environment of the large family constitutes a handicap to verbal development, and that this verbal retardation affects general mental development. If this were so, one would expect the negative correlation between intelligence test score and size of family to be more marked at later ages when the cumulative effect o environment begins to show itself; and this prediction was confirmed with tests applied at different ages The correlation between intelligence test score and size of family in an age-group of 1,236 children aged seven was − 0·26; in a similar age-group of 1,27 children aged nine it was − 0·29; and in four such age-groups totalling 5,168 children aged eleven i was − 0·33. The difference between the correlatio at age seven and at age eleven was significant a the 0·01 level, and was not attributable merely t incomplete families. In a group of 178 children wh were tested at ages seven, nine and eleven, confirmatory results were obtained, though the differenc between the correlations in this group was no significant because of the small numbers.

The results suggest that part of (but not all) th negative correlation of size of family and intelligenc test score, such as was found in the Mental Surve among children aged eleven, may be attributed t the environmental influence of the size of family o verbal ability and through it on general ment development. Fuller details of the results and the analysis will be published elsewhere.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 17

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria mbankment, London, W.C.2), at 5.30 p.m.—Discussion on "The eld of Application of Metal Rectifiers" (to be opened by Mr. S. A. evens).

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, .C.2), at 6 p.m.—Dr. P. W. Brian: "Microbiology" (Cantor Lec-res). (Further Lectures on November 24 and December 1.)

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, W.7), at 8.15 p.m.—Lord Rennell of Rodd: "Kimberley Division Western Australia".

Tuesday, November 18

UNIVERSITY OF LONDON (in the Anatomy Theatre, University ollege, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. Phyllis M. aberry "Gardening and Social Prestige in New Guinea".*

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (in the hemistry Lecture Theatre, Royal College of Science, Imperial stitute Road, London, S.W.7), at 2.30 p.m.—Dr. J. J. Lehr (Wagengen): "Sodium as a Plant Food".

EUGENICS SOCIETY (at the Royal Society, Burlington House, iccadilly, London, W.1), at 5.30 p.m.—Dr. Kenneth Hutton: "In-lligence Quotients and Differential Fertility—Some Observations om Winchester College".*

SCHOOL OF PHARMACY, UNIVERSITY OF LONDON (in the Meyerstein ecture Theatre, Westminster Medical School, Horseferry Road, ondon, S.W.1), at 5.30 p.m.—Prof. J. W. Cook, F.R.S.: "Organic hemistry at the Cross-Roads".*

ROYAL INSTITUTE OF CHEMISTRY, LONDON AND SOUTH-EASTERN OUNTIES SECTION (joint meeting with the POLYTECHNIC CHEMICAL OCIETY, at the Battersea Polytechnic, Battersea, London, S.W.11), 7 p.m.—Dr. H. J. Barber: "The Organic Chemist in Industry".

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, ondon, W.1), at 7.30 p.m.—Discussion on "Direction Finding in nimals" (Chairman: Prof. James Gray, F.R.S.; Speakers: Dr. . V. T. Matthews (Birds), Dr. H. W. Lissmann (Fish), Mr. D. Wragge orley (Insects)).

Wednesday, November 19

INSTITUTE OF METALS (at the Royal Institution, 21 Albemarle treet, London, W.1), at 9.45 a.m.—Symposium on "Properties of etallic Surfaces".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, .W.7), at 5 p.m.—Scientific Papers.

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene nd Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—r Ronald Fisher, F.R.S.: "The Expansion of Statistics" (Inaugural ddress of the President).

ROYAL MICROSCOPICAL SOCIETY (at the Cavendish Laboratory, ambridge), at 5.30 p.m.—Dr. V. E. Cosslett: "X-Ray Microscopy".

BRITISH ORNITHOLOGISTS' UNION (in the Lecture Hall, British useum (Natural History), Cromwell Road, London, S.W.7), at p.m.—Annual Scientific Meeting.

ROYAL INSTITUTE OF CHEMISTRY, LONDON AND SOUTH-EASTERN OUNTIES SECTION (at University College, Gower Street, London, .C.1), at 6.30 p.m.—Annual General Meeting; The President: Theory and Practice".

ROYAL METEOROLOGICAL SOCIETY, MIDLAND CENTRE (at the Birmgham and Midland Institute, Paradise Street, Birmingham), at 15 p.m.—Mr. H. Shaw: "The Recording of Earthquakes".

Thursday, November 20

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), 4.30 p.m.—Special General Meeting to consider the Annual Report Council; Prof. A. J. Kluyver, For.Mem.R.S.: "The Changing ppraisal of the Microbe" (Leeuwenhoek Lecture).

INSTITUTION OF MINING AND METALLURGY (at the Geological ociety, Burlington House, Piccadilly, London, W.1), at 5 p.m.—r. J. B. Dennison and Mr. W. W. Varvill: "Prospecting with the iamond-Drill for Lead–Zinc Ores"; Mr. R. J. M. Dixie and Mr. M. Dover: "The Development of Rotary Blast-Hole Drilling in e Jurassic Rocks of Lincolnshire".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, ondon, W.1), at 5 p.m.—Miss Katharine Tousey: "Audubon's merica" (colour film); Dr. E. Schelpe: "Vegetation in the Kangra malaya" (colour film).

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical ciety, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual neral Meeting; Prof. G. F. S. Temple, F.R.S.: "Theories and pplications of Generalized Functions" (Presidential Address).

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5 p.m.—Dr. D. H. R. Barton "The Chemistry of the Steroids". urther Lectures on November 27, December 4 and 11.)

INSTITUTION OF ELECTRICAL ENGINEERS, UTILIZATION SECTION t Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m. Mr. C. A. Cameron-Brown and Mr. P. G. Finn-Kelcey: "Electricity Farm Crop-Drying".

RESEARCH DEFENCE SOCIETY (in the Physiology Lecture Theatre, iversity College, Gower Street, London, W.C.1), at 5.30 p.m.—Howard Florey, F.R.S.: "The Advance of Chemotherapy by imal Experiment" (Twenty-first Stephen Paget Memorial Lecture).

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at the Building Centre, Store Street, London, W.C.1), at 6 p.m.—Dr. F. R. Jones "Alkali-Aggregate Interaction in Concrete".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (joint meeting with the FOOD GROUP, at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 6.15 p.m.—Discussion on "Technical Problems associated with Microbiological Standards for Foods."

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. L. H. Leavy and Mr C. J. Saunders: "The Design of a Wind Tunnel Balance".

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Mr. H. M. Powell: "The Chemistry of Intermolecular Compounds" (Tilden Lecture).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at the Liverpool School of Tropical Medicine, Pembroke Place Liverpool), at 7.30 p.m.—Laboratory Meeting.

Friday, November 21

TEXTILE INSTITUTE (at 10 Blackfriars Street, Manchester), at 3 p.m.—Sir Wallace Akers, F.R.S.: "The Chemical Industry and Textiles".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "The Electrical Conductivity of the Upper Atmosphere". (Chairman: Mr. J. A. Ratcliffe, F.R.S.; Speakers: Prof. S. Chapman, F.R.S., Prof. D. R. Bates, Prof. T. G. Cowling, F.R.S.)

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. W. A. W. Fox and Mr. D. Barnett: "The Vertical Reference in Navigation".

INSTITUTION OF MECHANICAL ENGINEERS (joint meeting with the APPLIED MECHANICS GROUP, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. K. J. B. Wolfe: "Recent Developments in the Machinability of Steel".

ROYAL SOCIETY OF MEDICINE, RADIOLOGICAL SECTION (at 1 Wimpole Street, London, W.1), at 8.15 p.m.—Dr. G. W. Blomfield "Experience with Two Million Volt X-Ray Therapy and a Preliminary Assessment of Clinical Results"; Dr. J. F. Mitchell: "Experience with 30 MeV. Synchrotron as a Radiotherapeutic Instrument".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. C. T. Wilkins: "The Comet".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

JOINT INTELLIGENCE BUREAU OFFICERS, Grade II, Ministry of Defence (with a university degree, preferably a good honours degree, or equivalent academic qualification or corporate membership of a professional body) for research work of university type on matters of defence interest—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 4169/52 (November 20).

EXPERIMENTAL OFFICER, Grade I, IN THE AERONAUTICAL RESEARCH LABORATORY, Fishermen's Bend, Victoria, to assist in the conduct of flight and laboratory tests on aircraft, to analyse the performance of components, and to prepare and calibrate the necessary equipment—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (November 22).

GRADUATE ASSISTANT SCIENCE MISTRESS at Lady Edridge Grammar School, South Norwood—The Chief Education Officer, Education Office, Katharine Street, Croydon, Surrey (November 22).

PHYSICIST TO THE RADIOTHERAPY DEPARTMENT—The Secretary, Romford Group Hospital Management Committee, Oldchurch Hospital, Romford, Essex (November 22).

PHYSIOLOGIST (with a good honours degree in physiology or an equivalent qualification, and research experience preferably involving the perfusion of isolated organs) for research on the bovine udder—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 52/11 (November 22).

RESEARCH STUDENT (university graduate, preferably a physiologist) in the Birmingham and Midland Eye Hospital, Birmingham, for work in connexion with hereditary ocular disease—The Secretary, Dudley Road Hospital, Birmingham 18 (November 22).

SCIENTIST, Grade III (with an honours degree in chemistry, with two or three years experience of precise analytical work, and interested in development of new methods of analysis, and investigational and research work), and a SCIENTIFIC TECHNICAL OFFICER, Grade III (qualified N.C. standard, and interested in electronics, workshop practice and general physics)—The Divisional Establishment Officer, National Coal Board, North-Western Division, 40 Portland Street, Manchester 1 (November 22).

SCIENTISTS (with a first- or second-class honours degree in electrical or mechanical engineering, or in physics, and preferably some research experience) for testing, development and research work in the laboratories and in the field in connexion with the generation, transmission and distribution of electricity—The Director of Establishments, British Electricity Authority, British Electricity House, Winsley Street, London, W.1, quoting AE/299 (November 24).

ASSISTANT LECTURER IN THE DEPARTMENT OF PHYSIOLOGY—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (November 29).

LECTURER IN THE DEPARTMENT OF PHYSICS—The Registrar, University College, Leicester (November 29).

ASSISTANT RESEARCH BIOCHEMIST IN THE SPECIAL UNIT FOR JUVENILE RHEUMATISM, for studies on connective tissue—The Hospital Secretary, Canadian Red Cross Memorial Hospital, Taplow, Maidenhead (November 30).

Scientists, Grade I (chemists, physicists or, preferably, physical chemists, with not less than a second-class honours degree and a good theoretical knowledge and acquaintance with modern laboratory instruments and techniques) to supervise research on a laboratory scale into known and novel methods of separating coal from shale and other unwanted materials (Ref. TT/559); Scientists, Grade II/III, with good honours degree, or equivalent, in chemistry, preference being given to physical chemists (Ref. TT/554); Scientific Technical Officers, Grade II/III (chemists or physicists, preferably of degree or H.N.C. standard), to assist in coal carbonization studies and associated analyses of coals, cokes and gases (Ref. TT/555); at the Central Research Establishment, Stoke Orchard, Cheltenham—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting the appropriate Ref. No. (December 1).

Research Assistant (honours graduate in mining or physics) to the Professor of Mining, and a Demonstrator (graduate in physics or mathematics) in the Postgraduate School of Mining—The Registrar, The University, Sheffield (December 6).

Plant Pathologist (with a Ph.D. in plant pathology, considerable research experience in the control of diseases of agricultural crops is preferable)—The Secretary, Tobacco Research Board, P.O. Box 1909, Salisbury, Southern Rhodesia (December 15).

Physicists and Chemists (with good honours degree, or equivalent) at the Central Research Establishment, Stoke Orchard, Cheltenham, for laboratory investigations on the surface characteristics and associated properties of coal and allied materials as applied to briquetting:—Scientist, Grade II, to take charge of the laboratory investigations (Ref. TT/560), a Scientist, Grade III (Ref. TT/561), and Scientific Technical Officers, Grade II (Ref. TT/562)—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting the appropriate Ref. No. (December 29).

Dean of Trinity College (University of Melbourne)—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 30).

Biochemist in the Clinical Laboratories of the Oldham Group of Hospitals—The Group Pathologist, Department of Clinical Pathology, Boundary Park General Hospital, Oldham.

Deputy Head of the Department of Aircraft Propulsion—The Registrar, College of Aeronautics, Bletchley, Bucks.

Engineer (Senior Scientific Officer grade) at a Ministry of Supply Experimental Establishment at Christchurch, Hants, dealing with design and development of military bridging and associated equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting B.453/52.

Irrigation Engineer in the Water Development Department, Tanganyika—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CSD.64/8/02.

Physicist interested in mechanics and engineering, for study and instrumentation of felting machines—The Director British Hat and Allied Feltmakers' Research Association, Stanley House, Manchester Road, Fairfield, Droylsden, Manchester.

Physicists or Electrical Engineers at the Royal Aircraft Establishment, Farnborough (*a*) in charge of small team developing electronic equipment for guided missiles (Ref A.281/52A), (*b*) for design and development in physics and engineering fields of guided weapon control, probably involving association with experimental missile trials and with radar and other electronic techniques (Ref. A.282/52A)—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

Research Assistant in the Electronics Section—The Research Manager, Motor Industry Research Association, Proving Ground, Lindley, Nuneaton.

Science Graduate (preferably in physics) to undertake abstracting of technical literature, preparation of literature surveys and other technical intelligence work—The Secretary, Research Association of British Rubber Manufacturers, 105 Lansdowne Road, Croydon.

Senior Physicist to work in the Spinning Department, in the first instance on the physics of the generation of tension in the yarn in ring spinning—The Director, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester 20.

Senior Physicist (with good honours degree plus research experience, and an interest in the application of research to practical problems) for investigations mainly on the elastic and viscous properties of rubbers—The Secretary, Research Association of British Rubber Manufacturers, 105 Lansdowne Road, Croydon.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Pitt Rivers Museum: University of Oxford. Occasional Papers on Technology, 5: Pictures of Ivory and other Animal Teeth, Bone and Antler; with a Brief Commentary on their Use in Identification. By T. K. Penniman. Pp. 40+20 plates. (Oxford: Pitt Rivers Museum, 1952.) 10s. [307

The Worker's Point of View: a Discussion of 'Reporting Back' based on a Study in a Coalfield. (Nationalized Industry Series 11.) Pp. iv+32. (London: Acton Society Trust, 1952.) 2s. [307

Research and Development in British Industry: a Survey of Expenditure on Industrial Research and Development in the Year 1950–51 made by the F.B.I. Industrial Research Committee. Pp. 19. (London: Federation of British Industries, 1952.) 1s. 3d. [68

Question: a Journal. Edited by H. Westmann. Vol. 4, No. 3: Freedom and Responsibility? By R. H. S. Crossman, the Earl of Verulam, A. H. Cartby and Edwin Barker. (Published for the Present Question Conference, Ltd.). Pp. 217–304. (London: Hammond, Hammond and Co., Ltd., 1952.) 2s. 6d. [13

PRESERVATION OF GEOLOGICAL SITES

BILSTON GLEN

"THE geologist is concerned fundamentally with observation, that is, with the systematic recording of phenomena as they present themselves to him"; so commented Dr. J. E. Richey in his presidential address to Section C (Geology) of the British Association at the recent Belfast meeting (*The Advancement of Science*, 9, No. 34, 122; September 1952). For this reason the geologist must continually be returning for study to the rock exposures that provide him with the material for his 'patterns of evidence'. The importance of preserving, so far as possible, geological sites of outstanding scientific and educational value was recognized by the Council of the eighteenth session of the International Geological Congress, by a unanimous recommendation, endorsed by the General Assembly of the Congress on August 30, 1948, to the governments of all countries represented at the Congress, to take legislative action, if they had not already done so, to safeguard such sites and to secure reasonable access to them[1].

The geological record has often been compared with an obscure and mutilated document, from the surviving remnants of which the geologist must piece together, as best he may, the history of the earth. Here and there natural sections yield exceptionally clear narratives of episodes in that history, and it is such sections that it is especially important to preserve as standards of comparison with more fragmentary records.

Such a standard section has been provided by the Bilston Burn where, about five miles south-south-east of the centre of Edinburgh, but less than a mile from the city boundary, it crosses the upturned strata on the western flank of the Midlothian syncline. Rising east of the Pentland Hills, the Bilston Burn passes under the Edinburgh to Peebles road at Bilston and enters a ravine which, about a mile farther east, attains a depth of about 150 ft. This ravine has come to be called the Bilston Glen; but the old name for it is Dryden, and this is the name by which it was known to Sir Walter Scott, who for a few years lived at Lasswade, in the same parish. Hugh Miller described it thus: "There is not a prettier dell in the south of Scotland than that of Dryden. . . . Dryden is a winding valley overhung by precipitous banks and stately wood, that opens into the wider valley of the Esk, and exposes, in its course, a series of strata singularly interesting to the geologist"; and, again: "I have already referred to the Marine Limestones of Dryden,—one of the best sections of the formation as developed in Scotland which I have anywhere seen"[2].

Dryden, or Bilston Glen, still retains much of its charm, and since Hugh Miller's time it has been frequently resorted to by geologists wishing to study the Scottish development of the Carboniferous rocks, not only from the Edinburgh district but also from all parts of Great Britain and from foreign countries.

Indeed, a geological excursion to the Edinburgh district can scarcely be considered complete without a visit to the Bilston Burn. Its easy accessibility and proximity to Edinburgh have made it especially valuable for demonstration to university students. The range of Carboniferous strata exposed in the glen is unrivalled by any other inland section in Scotland and by few elsewhere in Great Britain. This is due to the prevailing high easterly dip, which averages more than 45°, the Bilston Burn crossing the outcrops nearly at right angles to the strike. Thus, in the stretch of about a mile and a quarter east of the Edinburgh–Peebles road, the strata traversed by the Bilston Burn range from the top of the Calciferous Sandstone Series, through the Lower Limestone, Limestone Coal and Upper Limestone Groups, into the Millstone Grit (Roslin Sandstone), comprising a thickness of nearly 3,400 ft. of beds. Though more spectacular, not even the famous section of the Avon Gorge at Bristol reveals so great a thickness, or a much greater stratigraphical range, of Carboniferous strata.

Exposures in the Bilston Glen are not continuous; but they are sufficiently numerous for a tolerably complete record to have been compiled over the years during which the section has been studied—a record, however, which is even now being amended and added to. Many fossiliferous bands have been located and collected from, and among the most interesting are those in the lower part of the Millstone Grit, the fossils of which closely resemble forms found in the Coal Measures of Nebraska and Illinois, from which circumstance the assemblage has been called the 'Nebraskan Fauna'[3]. The known fossil horizons in the Bilston Glen include nearly all those named bands which serve as index beds in the Scottish Lower Carboniferous sequence; but the presence of some of these bands has only quite recently been established. A natural section such as this, with an active stream and unstable banks, must change somewhat from decade to decade; hence, so long as the glen remains accessible, there will always be the possibility of new discoveries.

The Bilston Glen, then, provides a type section with which to compare the variations of the Lower Carboniferous sequence elsewhere in Scotland. This is not only important from the purely scientific point of view, but is also of great practical value for the mining industry, for the comparison can be made with sections in mine-roads and with the cores of exploratory borings. The utility of such a type section in the training of students who may later apply their stratigraphical knowledge to the solution of mining problems should require no emphasis.

Nevertheless, more than half of this type section is threatened with obliteration. A new colliery, named (perhaps with unconscious irony) "Bilston Glen Colliery", is being sunk on the north side of the Bilston Glen to work the large reserves of coal in the Limestone Coal Group of the district, and it has been planned to dispose of the spoil by filling up the adjacent Glen. Since, in the late summer of 1950, this project became generally known, protests against the spoliation of the Bilston Glen have been registered by scientific bodies, including the Geological Societie of Edinburgh, Glasgow and London and the Britis Association for the Advancement of Science. Mindful no doubt, of the threatened loss of a feature o natural beauty in an area already losing its rura character, the Association for the Preservation o Rural Scotland supported the protest made by th Edinburgh Geological Society. Further, the Natur Conservancy took up the cause of the Bilston Gle in an endeavour to secure its conservation as Nature reserve.

So far, however, these efforts seem to have resulte in no more than a temporary and partial reprieve By a decision of the Minister of State for Scotland made in March of this year, the National Coal Boar has been given permission to use part of the Glen fo the dumping of colliery refuse during the next ten o fifteen years. At the end of this period the possibilit of transferring dumping to another site is to be considered; but, if this is found to be impracticable the Coal Board is to be allowed to use an adjacen part of the Glen, farther down stream, and will b asked to consider whether a third portion, west o that to be used first, could also be filled in with spoil If it is not thought practicable to use another site fo dumping now, it is, perhaps, scarcely likely that i will seem more practicable ten or fifteen years hence when the Coal Board has already been using part o the Bilston Glen for that period. The Minister' decision thus seems virtually to condemn a larg portion of the Glen to destruction. This include what is, perhaps, the most valuable part of th geological section, comprising more than 2,000 ft. o strata and including the whole of the Lower Limestone and Limestone-Coal ("Edge Coal") Groups.

All this part of the Bilston Glen would scarcel accommodate as much as half the total amount o spoil that it is estimated will be produced during th hundred years life of Bilston Glen Colliery. Soone or later, then, some other means of disposing of th refuse must be devised. Is it too much to hope tha even now, more far-sighted counsels may prevail and that the picturesque Dryden, with its class geological section, may be spared for posterity ?

HORSES

Horses

The Story of the Horse Family in the Modern Wor and through Sixty Million Years of History. I George Gaylord Simpson. Pp. xxiv+247+32 plat (New York and London: Oxford University Pre 1951.) 40*s*. net.

SO much of human history has been determined b the existence of domesticated horses that the animals have gained a unique place in folk-lore a in the affections of many men. The horse w apparently domesticated early (probably many tim in the area of distribution of wild horses from Euro to China, and it is probable that selective breedi has long been practised to produce horses fit not only for ordinary life, but also for war. Arabs and Genghis Khan's 'Golden Horde' owed their conquests to well-designed cavalry tactics, and these were dependent on speed and toughness.

Of such specialized breeds the most distinguished is the Arabian. Long inbred in the desert, with pedigrees carefully kept, the Arab horse played its essential part in the development of the Thoroughbred; and the Thoroughbred horse has contributed to light horses all over the world.

G. G. Simpson gives in this book a very condensed but admirable account of the domestic horses, especially of Britain and the United States. He then passes on to consider the colour of horses, especially in American use where there are names—Pinto, Appaloosa and Palomino—which are strange to an Englishman. A Palomino is a horse with a silver mane and tail and a golden body, its body shape being undefined; none the less, Dr. Simpson points out that two independent associations, of the nature of breed societies, exist in the United States. It seems very doubtful if the Palomino colour can exist in a homozygous form; it is normally heterozygous and cannot breed true. Simpson gives a very simple and clear account of the genetics of the condition as determined by W. E. Castle.

From here the book goes on to describe the history of the horse in geological time. The first attempt to do so was in 1872 when T. H. Huxley brought together *Palæotherium*, *Anchitherium*, *Hipparion* and *Equus* as animals which, put in the order of age, formed a graded series in the structure of their teeth and feet; and he suggested that this might be a real example of the evolution of an animal. A year later Kovalevsky, after a much more detailed study, agreed with Huxley and in 1876 carried the matter still further, still using European materials. In fact, none of these animals is in the direct line of the horse; they are aberrant lateral twigs, which nevertheless conform in many characters to true horse ancestors of the same, or often a slightly earlier, stage. Actually, in 1874, O. C. Marsh, of Yale University, claimed to have a series of fossils which lay in the direct line of descent and supplied every important form. In 1876 Marsh demonstrated these materials to Huxley, who immediately accepted his conclusions.

Since then, immense collections of fossil horses and horse ancestors have come from all the continents except Australia, and nearly all vertebrate palæontologists have published something about them. Under the influence of H. F. Osborn, the American Museum of Natural History became the great centre of work on these animals, and for many years W. D. Matthew's little guide to the Museum collection has been the best account of the whole story. This booklet, now out of print, is obsolete, and in the present very readable volume Dr. Simpson gives a most admirable account of the whole history—not of course in detail, for that would mean many thousands of pages of text and of figures, but in outline. He considers not only the actual structural changes, but also the functional effect of these changes in increasing the weight which can be supported by the food which can be ground up by the dentition, and the significance of the structural changes in the feet.

The book is thus authoritative, wide-ranging and easy to read, and it should be read by everyone who is interested in evolution and the mechanism by which it has been brought about.

D. M. S. WATSON

PROGRESS IN NUCLEAR SCIENCE

Annual Review of Nuclear Science

Vol. 1. Pp. x+645. (Stanford, Calif.: Annual Reviews, Inc.; London: H. K. Lewis and Co., Ltd., 1952.) 6 dollars.

ONE index of the increase in the rate of accumulation of scientific information is the post-war efflorescence of reviews and surveys. In physics alone, for example, there have appeared "Progress in Metal Physics", "Progress in Biophysics", "Progress in Cosmic Ray Physics", and so on. Annual Reviews, Inc., of Stanford, California, have for some time published "Annual Reviews of Biochemistry"; now a new series commences, the "Annual Review of Nuclear Science".

The objective of the editors is the preparation of a series of annual review volumes covering the most important developments in the field of nuclear science each year. For the first year (1950), they have certainly cast their net wide. Thus, while about half the book is devoted to physical topics, the other half includes the separation of stable isotopes; metallurgy; actinide elements, and analytical nuclear chemistry; radioisotopes in chemical systems, in biochemical research and in soils research; geochemistry; stable isotopes in biochemical research; and the genetic and biological action of radiation. Of these, some (especially the article on progress in metallurgy) are clear and concise; but in general the articles are too technical to satisfy the average physicist, while probably not detailed enough to satisfy, say, the plant biologist who would otherwise feel that the book is heavily weighted in favour of the other sciences. A better approach might be to restrict individual volumes to individual fields of nuclear science.

The volume, therefore, is presented to that versatile individual, the nuclear scientist, and one might expect the level of the average essay to be that of postgraduate standard. The approach of the various authors, however, varies widely. Thus, on one hand, the article on energy-levels of light nuclei goes to the length of explaining the meaning of the notation $^7\mathrm{Li}(d\alpha)^5\mathrm{He}$; whereas, on the other hand, that on the theory of nuclear structure is addressed to the specialist rather than to the general reader.

Nevertheless, the general impression is that the venture is successful and the effort well worth while. The volume makes an excellent start with an article on meson physics, which is an admirable survey of the subject; supported later by one on the nuclear interaction of cosmic rays. Stable isotopes are discussed in three articles, and high-energy accelerators in five; the essay on the detection of nuclear particles is concise and practical. That on nuclear moments is a little disappointing—one feels that a fascinating field is rather summarily dismissed. In contrast, the article on atomic and molecular spectroscopy is a clear exposition of recent developments in a well-ploughed field. Finally, there is an essay on low-temperature phenomena, which is perhaps an interloper in a volume on nuclear science; but it is so well written, in its sketch of background and review of recent development, that its inclusion is amply justified.

The format is excellent and errors few. No British reader, however, will fail to be interested to learn (p. 178) that a 140-MeV. synchrotron is under construction at "Oxford University, Cambridge, England".

W. D. ALLEN

LAND RECLAMATION

Reclaiming Land for Agriculture

By Moses Griffith, J. F. H. Thomas and R. Line. (Agricultural and Horticultural Series.) Pp. 119+16 plates. (London: Crosby Lockwood and Son, Ltd., 1951.) 12*s*. 6*d*. net.

TO those who can recall the time when meat, cheese and eggs were basic articles in the Englishman's diet, this book will bring hope that their children may live to see those conditions restored. The wastage of our greatest, and potentially inexhaustible, source of wealth—the land—is a national scandal. Mr. Moses Griffith estimates that there are five million acres of hill and moorland alone in Britain "capable of very substantial improvement", and he and Messrs. J. F. H. Thomas and R. Line show that the task of reclamation with modern implements and technique would not be difficult on the hill land, the chalk land and the fen and silt land which they respectively discuss.

Sir George Stapledon, in a comprehensive introduction, points to the very high cost of land reclamation and emphasizes the economic importance of regional planning, and of intensive study of plant and animal ecology, not forgetting human requirements; for unless men and women find social satisfaction on the reclaimed land, it will revert to waste. It is to be hoped that a people which spent nearly £40 million on almost fruitless land reclamation in East Africa will not be deterred by the initial cost from replenishing its larder from its own soil.

It is on the intrinsically infertile, and often inaccessible, hill lands that the economic factor is most intractable. The crawler tractor and other machines have, however, greatly facilitated the task of cultivation, and the aeroplane should equally help to solve the problem of fertilizing these lime- and phosphate-starved soils. Work at Aberystwyth has shown that remarkable improvement can often be effected by ploughing and reseeding with improved herbage, usually after a pioneer crop like rape which is grazed to provide dung and consolidation of the soil by stock. Mr. Griffith leaves the impression that, although many intricate questions remain unanswered, enough success has already been achieved to make very large-scale reclamation of hill land a practical proposition now.

Reclamation of chalk land presents rather easier problems. Much of the land has been highly farmed with sheep in the past and has only recently become partly or completely derelict. Considerable areas were cultivated to exhaustion during the First World War, and these could be restored to productivity fairly easily with adequate fertilizing. Among the major tasks are the clearance and disposal of scrub growth on abandoned land, much of it of high productivity, and the restoration of the rich valley pastures. There is scope for intensification of both arable and livestock farming, and the appropriate land management is better understood than is the case on mountainous hill land.

In the Fen country "the cost of reclamation of the fen is not such an important consideration as the returns per acre that can be expected from this very exceptional soil". Around the Wash there are a hundred square miles of this country awaiting enclosure and development. Good drainage is the key to fenland farming, and much reclaimed land has been allowed to go derelict through neglect of drains. Methods of reclamation and management are well understood, and what are chiefly needed are men, money and machinery. It is to be hoped that the Government will give high priority to this first line of defence—at least as vital to our security as rearmament, for the imperative need to grow our own food will always remain, whatever the international outlook.

G. V. JACKS

THE HORMONES

A Symposium on Steroid Hormones

Edited by Edgar S. Gordon. Pp. xiii+396. (Madison, Wis.: University of Wisconsin Press, 1950.) 6.50 dollars.

Recent Progress in Hormone Research

The Proceedings of the Laurentian Hormone Conference. Vol. 5. Edited by Gregory Pincus. Pp. viii+537. (New York: Academic Press, Inc., 1950.) 8.80 dollars.

The Hormones

Physiology, Chemistry and Applications. Edited by Gregory Pincus and Kenneth V. Thimann. Vol. 2. Pp. ix+782. (New York: Academic Press, Inc., 1950.) 12.50 dollars.

Vergleichende Physiologie

Von Prof. W. von Buddenbrock. Band 4: Hormone. (Lehrbücher und Monographien aus dem Gebiete der exakten Wissenschaften: Reihe der experimentellen Biologie, Band 9.) Pp. 492. (Basel: Verlag Birkhäuser, 1950.) 47.50 Swiss francs.

THE first three of these four volumes were published in the United States in 1950, and to some extent cover the same ground. The fourth is a German work which deals with less-recent endocrinological knowledge.

The "Symposium on Steroid Hormones" is a report of a conference which took place at the University of Wisconsin in 1949, and is concerned with the chemistry, biosynthesis and metabolism of steroid hormones and with their physiological effects. Some of the facts presented at the conference have not previously been published, so that, in addition to a general review, the volume edited by Dr. E. S. Gordon will need to be referred to as a source book of original observations. The ground covered by the contributors to "Recent Progress in Hormone Research", Vol. 5, which is a report of the proceeding of the Laurentian hormone conference for 1949, i much the same as that which was explored at th Wisconsin conference for 1949, and again a larg number of the contributions deal to a considerabl extent with new observations.

Neither of these meetings was concerned to cove the whole field of hormone research. This is th purpose of the two volumes published under the titl of "The Hormones", and edited by Gregory Pincu and Kenneth V. Thimann. Vol. 1 appeared in 194 and dealt with plant hormones; hormones i invertebrates; the internal secretion of the pancreas and various aspects of the steroid hormones, as we as with the chemistry of the anterior pituitary hor mones. Vol. 2 deals with the physiology of ovaria hormones; of androgens; of the adrenal cortex; the thyroid; of the pituitary hormones; as well with the chemical control of nervous activity; an concludes with a section on clinical endocrinolog In their preface, the editors point out that any wor in which separate sections are contributed b different experts runs a risk of being disproportionate in its emphasis. While admitting this danger, they also suggest that the two volumes for which they are responsible nevertheless provide a fairly complete presentation of the subject "at the research level". They can be confident that this is so, and students of endocrinology are greatly in their debt for having undertaken so formidable a task.

Vol. 4 of "Vergleichende Physiologie", by Prof. W. von Buddenbrock, of the University of Mainz, is in an entirely different class. Its purpose is not clearly stated, and it is far less comprehensive in its references to modern literature than any one of the three American volumes referred to above. It is the fourth of a series on comparative physiology, of which the first two were written before the Second World War, and the third was in the press when the War began. The present volume was undertaken at a time when the author did not have access to work that was being carried out either in Great Britain or in the United States, and was brought 'up to date' during only a five-week stay in Switzerland, when Prof. von Buddenbrock had access to the more recent literature. Although published in 1950, the result is that there is an almost negligible record of work published after 1946. The book has a zoological, as opposed to an endocrinological or clinical, orientation, and will be of value to research workers in American and British laboratories who wish to obtain a synopsis of endocrinological research carried out on the Continent of Europe up to the year 1939.

THE PHASE RULE

Principles of Phase Equilibria

By F. E. W. Wetmore and D. J. LeRoy. (International Chemical Series.) Pp. x+200. (London: McGraw-Hill Publishing Co., Ltd., 1951.) 30s.

The Phase Rule and Heterogeneous Equilibrium

By Prof. John E. Ricci. Pp. xi+505. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1951.) 90s. net.

THE introduction of the phase rule into chemistry dates from 1884, when Bakhuis Roozeboom, working in the laboratory of van Bemmelen in Leyden n hydrates of sulphur dioxide, had his attention directed by van der Waals to a rather obscure and brief passage in a paper by Willard Gibbs, published n 1876, which contains the key to the systematic tudy of heterogeneous equilibria. Since then it has proved of inestimable service in many fields. The rst intelligible account of it was given by Roozeoom, and the clear survey by Findlay is still one of he best books for the student. The two books here nder review are intended to help students to undertand and appreciate what is undoubtedly one of the major branches of physical chemistry. Many find the ubject rather unattractive in comparison with other elds of study, since it offers no scope for hypotheses nd does not involve what may be called modern spects of the science, based on new knowledge of tomic and molecular structure. Still, no one can ford to neglect a subject which can and does play n important part in chemical industry, and a good ook on it should always find a welcome.

F. E. W. Wetmore and D. J. LeRoy's book is oncerned mainly with fundamental principles, resented in a form based on experience and making use of thermodynamics. It is intended for students in other subjects, such as arts and engineering, as well as chemical students. The treatment is elementary, and the bright students may find parts of it rather dull, since some points which may be almost obvious are dealt with in some detail. It does, however, reach four component systems, and there is a brief appendix on the thermodynamic basis of the phase rule and on partial molar quantities. The book is sound, but seems to have no obvious superiority over existing ones.

The book by J. E. Ricci, who is an authority in the field, is more ambitious and detailed, and hence, probably, more attractive. It begins with a thorough examination of the basis of the phase rule which all readers will find interesting. It is, however, doubtful if much more has been added to the clarification of the well-known difficulty of the definition of the number of components of a system. This is purely a matter of mathematical book-keeping, and most teachers find that the more this is emphasized and the less concession is made to beginners who feel that they ought to have some 'reasons' given them, the quicker the pace in learning. Another point is the introduction of continuous miscibility at the start, heterogeneous systems with pure phases being brought in as special cases. This is done in some other books, and not all will agree that it is the best way of beginning the subject. It may be the ideal way; but that is a different matter. The book deals with all the important aspects of the subject in a masterly way, and will be regarded as an authoritative monograph. All the important methods of graphical treatment are explained, and I have missed nothing which could be expected to be found in an advanced book. The diagrams are clear and attractive. I think that the subject is best taught in relation to actual systems, and this is done in the book. It makes the subject more real to the student and makes him aware of its value and scope, so that he takes an interest in what might otherwise be rather formal and dull to him. This book is certain to become a standard and should be sure of a warm welcome by those who can afford it.

J. R. PARTINGTON

COLOUR

Colour

In Theory and Practice. Edited by H. D. Murray. A new edition, revised, enlarged and re-written by R. Donaldson, V. J. Francis, P. Holliday, R. G. Horner, N. Laycock, L. C. Thomson, G. T. Winch, and the Editor. Pp. xiii+360+27 plates. (London: Chapman and Hall, Ltd., 1952.) 70s. net.

IT is thirteen years since the first edition of "Colour" appeared (see *Nature*, 144, 227; 1939), and the present book differs very considerably from the original. Mr. H. D. Murray has enlisted seven collaborators instead of his original one. A medical man, for example, has rewritten the chapters concerning the anatomy and physiology of the human eye, and included new material to give a more comprehensive survey. Other specialists have similarly revised and extended the treatment of their own fields.

The consideration of the fundamental physical and chemical aspects of radiation comprises a little less than one-third of the text. Here the authors have devoted some space to atomic physics as a background, and have gone somewhat outside the strict limits of 'colour'. The book has gained rather than lost by this liberal interpretation of the subject, which is also apparent in other places, but some such title as "Visible Radiation" might, therefore, have been more appropriate. In the review in *Nature* of the first edition, it was suggested that the survey of coloured substances could advantageously have been combined with the chapter on the chemistry of colour, but it is now even more completely divorced, as an appendix. Chemical indicators are barely mentioned, despite their great interest.

Human vision, and subjective aspects of light and colour, are accorded an even more expanded treatment. As many workers in other branches of science, and in commerce and industry, never aspire to more precise colorimetric tools than colour charts, further considerations of the limitations and virtues of the popular colour dictionaries would have been welcome.

The third section is highly technical, discussing light sources from sun to candle, from arcs to fluorescent lamps, and the complicated apparatus and methods of modern light and colour measurement. A penultimate chapter concerned with the psychology of colour follows as comparatively light relief.

A very few pages headed "Colour in Nature" are unworthy of the rest of the book; they provide not a single clue to the relevant botanical, and only three references to the zoological, literature. It is a pity that one or more biologists were not included in the team of authors.

The second edition of "Colour" includes most of the original matter, much rearranged, and a good deal of new text, with additional figures. (Although the first edition only claimed three colour plates to the eight of the present book, in fact both have the same number of coloured illustrations, and only two of these have been substituted.) Changes in terminology are to be noted, and the new Appendix 3 is a valuable extract of definitions, for the most part internationally accepted, from the Physical Society's 1948 Report on Colour Terminology. Separate bibliographies for each chapter now replace scattered references in the text—a great improvement. A dual pagination with index references on a chapter rather than book basis seems a needless irritation. The amplified and revised text is, of course, more up to date and satisfactory to the specialist, and more valuable to him as a work of reference; almost inevitably it has also become less easy to read for the non-physicist seeking a comprehensive guide to the whole field of colour.

The first edition was criticized as expensive at 25*s*. After making allowance for the augmented text (but smaller format and more ordinary binding), even by to-day's standards the new edition seems no cheaper.

S. Clay

AGRICULTURAL PHYTOPATHOLOGY

Disease in Plants

An Introduction to Agricultural Phytopathology. By the late Dr. Neil E. Stevens and Prof. Russell B. Stevens. (Manual of the Plant Sciences, Vol. 1.) Pp. xx+219. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson, Sons and Co., Ltd., 1952.) 4.75 dollars.

THIS manual, written by two distinguished American pathologists, father and son, is based on a series of lectures, planned as self-contained chapters, on the general principles of plant pathology. It does not treat of specific diseases and pathogens, but the entire subject-matter forms a comprehensive and valuable introduction to plant pathology designed, as the authors state, for the general reader as well as for the student and professional pathologist.

Stress is laid at the outset on the seriousness of the world food problem to-day, on measures of increased production and of possible preventable losses through disease control. These topics are discussed as part of the whole food situation in relation not only to food crops but also to the healthy production of timber stands and fibre plants as well.

Presumably for the benefit of the general reader, an early chapter (there are twenty in all) is devoted mainly to the anatomical structure and physiology of the healthy green plant, root, stem and leaf, this being followed by descriptions of pathological effects in these organs. The diagrams illustrating the normal anatomy are good and clear, but the same cannot be said of the few photomicrographs showing features of morbid anatomy.

Having already mentioned that bacteria and fungi are the principal instigators of disease, the authors, instead of first giving detailed consideration to these organisms, which are so easily demonstrable in affected tissues, proceed as early as in their third chapter to a consideration of viruses as agents of plant disease. Then follows a comparatively short account of bacteria and fungi, meagrely illustrated, this section closing with a table of classification of phytopathogenic forms. The occurrence, chemical nature, multiplication, mutation, transmission, symptoms, etc., of viruses and their effects are given brief but excellent treatment, this chapter being well illustrated in respect of symptoms of virus diseases. A section is also devoted to parasitic and hemiparasitic seed-bearing plants, and to injurious nematodes and insects. Excellent consideration again is given to nutritional and meteorological factors and to chemical injury in relation to the incidence of disease, with a full citation of relevant literature appended.

It is refreshing to find an entire section being devoted to the significance of such factors as the abundance and uniformity of the host plant when grown in close formation or pure stands, in contrast to growth in mixed culture as conducive to epidemic attacks; growing conditions—temperature, light and nutrition; and disease escape—resistance, tolerance and immunity. In the section on epidemiology which may well have appeared earlier in the manual the qualities, reproduction and dissemination o micro-organisms are treated, brief consideration being given to methods of host-penetration and survival o the pathogen; further discussion of the parasite in respect of variation and physiological specialization is resumed in later sections.

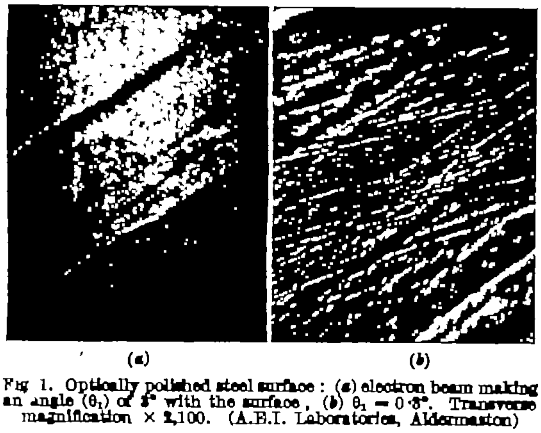
Eight chapters of the manual are devoted to the subject of disease control, embracing such topics a the economy of disease control, chemical treatment seed and soil treatment, crop rotation, sanitation breeding, 'market' pathology (harvest losses, low temperature storage, care in handling) and the incidence of 'new' diseases. This excellent manua apparently the first of a series on plant sciences closes with a plea for greater public support o agricultural research and for the encouragement o intelligent co-operation between grower an pathologist as contributory in no small measure t the success of the world-wide campaign against foo shortage and disease.

S. G. Jones

ELECTRON MICROSCOPY OF SOLID SURFACES

THE normal type of electron microscope allows specimens to be examined by transmission only. The possibility of image formation with electrons scattered from a solid surface was early investigated by Ruska and Müller[1], with normally incident electrons, and by von Borries[2] with grazing incidence. The latter method proved more effective and 'reflexion' micrographs were obtained from a variety of metal surfaces[3]. The development of replica techniques provided a simpler means of investigating topography, applicable in many circumstances, and the reflexion method was temporarily abandoned. However, the widening application of the electron microscope showed the need for a means of continuously observing a surface at high resolution—for example, under chemical treatment or at high temperature. In 1948 an investigation of the possibilities of the reflexion electron microscope was begun in several centres independently: in the U.S.S.R.[4], in the Cavendish Laboratory, Cambridge[5], and in the Engineering Laboratory, Cambridge (by a scanning method). Soon afterwards, the construction of a reflexion instrument was begun at Toulouse, and more recently at least two standard electron microscopes have been adapted to reflexion operation. The progress of most of these projects was reported at a special session of the meeting of the Electron Microscopy Group of the Institute of Physics, held at the H. H. Wills Physics Laboratory, University of Bristol, during September 16–19, which gave a convenient opportunity for assessing the potentialities of the reflexion technique. The parallel development of surface investigation by means of electrons emitted thermionically or photoelectrically was not surveyed, but it is useful to include here a method using ionic bombardment to excite emission.

In the 'reflexion' electron microscope only a small part of the electrons experience reflexion in the true sense, the majority being scattered irregularly from the irradiated surface. If the beam is incident at a grazing angle of a few degrees and the portion 'reflected' at a similar (but not necessarily identical) angle is collected in a system of electron lenses, as in a normal electron microscope, it is found that micrographs of good contrast can be obtained at a useful magnification of several thousand times. M. E. Haine, W. Hirst and A. E. Ennos (Associated Electrical Industries Research Laboratories, Aldermaston) discussed the scattering of electrons of the relevant speed (50–100 kV.) by a solid surface, with particular attention to angular distribution and energy loss. The latter is important, as it introduces a chromatic spread into the reflected beam, which severely restricts the attainable resolution owing to the large aberration of the lenses. From measurements of the unsharpness of the image at high magnification, the loss of energy ΔV was found to extend to about 150 V. With the type of objective lens and angular aperture used in transmission microscopy, the corresponding resolution would be about 400 A., but by using a very small aperture a value less than 50 A. might be attained. Exposure times would then become inconveniently long owing to the relative inefficiency of reflexion and the small aperture. At present, it can be kept to a few seconds by using a normal aperture and the most intense illuminating beam available.



(a) (b)

Fig. 1. Optically polished steel surface: (a) electron beam making an angle (θ_1) of 3° with the surface, (b) $\theta_1 = 0 \cdot 3°$. Transverse magnification × 2,100. (A.E.I. Laboratories, Aldermaston)

The distribution with scattering angle fell less rapidly than expected, falling to about 10 per cent at 10° to the surface. Hence the optical axis of the microscope can be sufficiently inclined to that of the illuminating system to avoid reception of the direct beam without undue loss of brightness in the image. When the surface is optically very smooth, it is found that best results are obtained with a small incident grazing angle ($\theta_1 < 1°$) and a moderate angle of view θ_2 (4°–10°). It is advisable to keep the latter as large as is compatible with exposure requirements, so as to minimize foreshortening of the image. Haine, Hirst and Ennos have investigated an optically polished steel flat, using an adapted Metropolitan-Vickers *EM*3 instrument with an electron gun of continuously variable tilt. Extremely fine detail becomes visible on reducing the grazing angle from 3° to 0·3° (Fig. 1). It is estimated that irregularities in height of the order of 40 A. should be directly detectable by this means. In the opening contribution, entitled "The Evaluation of Surface Topography", Hirst pointed out that surface relief of long period is readily revealed, which would not give adequate contrast by the replica method in transmission even if the field of view were sufficiently large. A crystallographically informative type of diffraction micrograph can be taken by selecting, with an aperture in the back focal plane of the lens, the diffracted beam corresponding to a true Bragg reflexion. A bright-field image of the correctly oriented crystals is then obtained, superimposed on the normal reflexion picture.

Prof. O. Fert (University of Toulouse) described a reflexion microscope in which the inclination of the beam is controlled with magnetic deflecting coils. It is designed to operate up to 250 kV. and has already been used at 100 kV.; an intermediate lens permits electron diffraction operation. The object holder allows every required motion of the specimen, including rotation in azimuth. A resolution approaching 500 A. has been obtained with an aperture of 5×10^{-4} (Fig. 2). He finds that better results are obtained at 100 kV. than at 50 kV., probably owing to the improved value of $\Delta V/V$, since ΔV does not depend on V so long as multiple collisions are not important. Prof. Fert discussed means of restoring

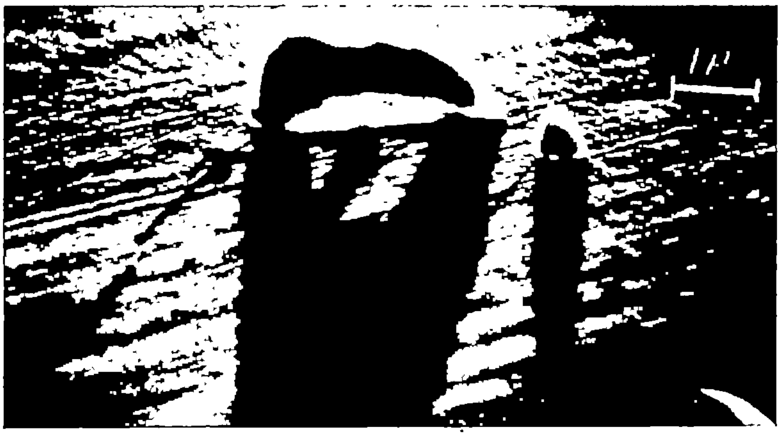


Fig. 2. Surface of polished aluminium, with foreign particles; $\theta_1 = 2°$ and $\theta_2 = 4°$. Transverse magnification × 10,000. (Physics Laboratory, University of Toulouse)

to the image its original aspect, by providing differing magnifications in and across the plane of incidence, with crossed cylindrical lenses, either in the objective itself or in the photographic enlarging system. Alternatively, the recording plate or the printing paper could be inclined to the optic axis in order to compensate the foreshortening.

A similar instrument built at the Cavendish Laboratory, Cambridge, under a project of the British Iron and Steel Research Association, was described by Dr. V. E. Cosslett and D. Jones. It is designed to operate up to 90 kV. with an objective of long working distance ($f = 15$ mm.) so that metallurgical specimens of convenient size can be accommodated. An intermediate diffraction lens is included, and the dimensions of the imaging system are calculated to eliminate distortion and chromatic defects from the diffraction image[5]. The illuminating angle can be mechanically varied from 0° up to 10°, and inclination and translation of the specimen is possible. A large object-chamber is provided so that experiments can be carried out at high temperature or during chemical or mechanical action on the surface of the specimen. Reflexion micrographs of typical metallurgical structures show a resolution of 600–700 A.; an objective of smaller chromatic error is being designed. Comparison with optical photographs assists in interpreting the foreshortened pictures, but it may be preferable to leave them in this state, where the relief is immediately obvious, rather than to correct them to the condition of vertical viewing.

The effect of the electron beam on the specimen must be considered in reflexion as in transmission, though it appears that the danger of artefacts is not here so serious. The temperature rise is not so great, owing to the large thermal capacity and good conductivity of the specimen, but might be serious in non-conductors; the latter can be made sufficiently conducting to avoid charge accumulation by depositing a thin layer of metal on them. But even with metals a slow etching process occurs, either by direct ejection of metal ('electronic sputtering') or by temperature rise sufficient to give thermal etching. Cosslett and Jones showed that the appearance of a ruled grating changed considerably after long exposure (~ 1 hr.) to the electron beam (Fig. 3).

On the other hand, a carbonaceous layer is produced on the irradiated part of the specimen unless the surface temperature is high, but not rapidly enough to obscure detail within the resolving power attainable. Indeed, the 'shadows' thus formed behind projections on the surface have the useful property of allowing ready identification of the irradiated region in subsequent optical examination, as well as estimation of the height of the projections, as pointed out by Dr. J. W. Menter (Physics and Chemistry of Surfaces Laboratory, Cambridge). He described the experience gained with a reflexion head of fixed inclination fitted to an *EM*3 instrument, and also discussed the attainable resolution and the interpretation of reflexion micrographs. A variety of metallic and crystalline surfaces have been examined with an aperture of 3×10^{-3} and a resolution approaching 400 A.[6]. In this way, cleavage steps on mica and growth spirals on silicon carbide have been observed. Slip lines on cadmium show well, if orientated across the line of view, and a cleavage surface of zinc gave particularly striking results (Fig. 4). Very slight inclinations of the surface (~ 4°) across a twin are clearly visible; the black lines across the field of view are cleavage steps. Menter indicated also some possible applications to the study of the surface of biological objects.

A short account of the work in the U.S.S.R. on reflexion microscopy[4] was given in another session of the conference; it follows very closely the developments described here. A rather different system due to Möllenstedt (A.E.G.–Zeiss) was briefly described by Prof. O. Scherzer (Technische Hochschule, Darmstadt). It employs an ion beam, incident

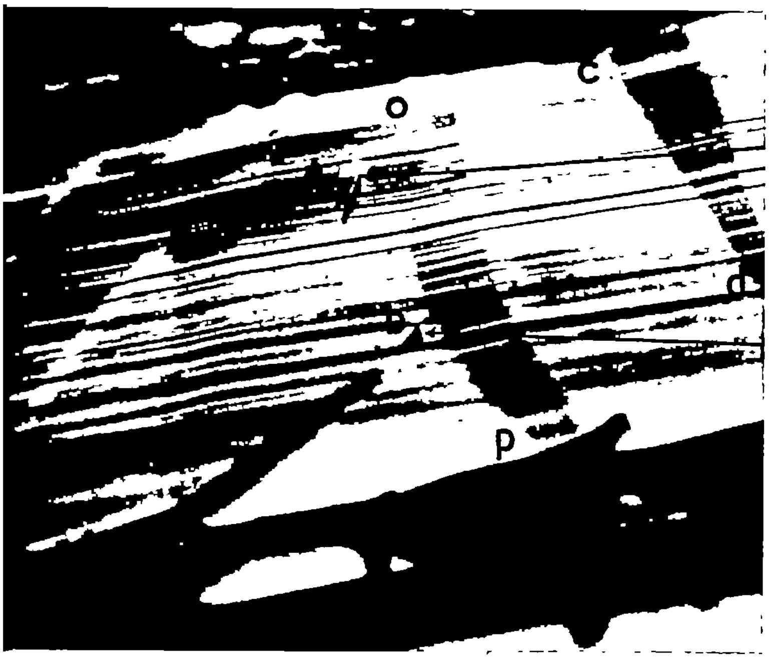
Fig. 3. Nickel-plated brass ruled at 5-μ spacing in both directions in upper part of field, but in only one direction in lower part: (a) when first exposed to electron beam, $\theta_1 = 2\frac{1}{2}°$ and $\theta_2 = 7\frac{1}{2}°$; (b) after exposure of about 1 hr. in beam, $\theta_1 = 1\frac{1}{2}°$ and $\theta_2 = 8\frac{1}{2}°$. Transverse magnification × 1,600. (Cavendish Laboratory, Cambridge)

at 45° on the specimen surface, to excite emission of electrons, which are then collected by an electrostatic lens at a voltage of 30 kV. Micrographs at a resolution of about 1000 A. have already been obtained. The chief advantages are that the surface is viewed normally so that no distortion occurs, and that the voltage spread of the emitted electrons is only about 3 V., so that chromatic aberration is negligible.

In the usual type of electron microscope a macroscopic area of specimen is illuminated, and the whole of the image is projected at once. D. MacMullan (Engineering Laboratory, Cambridge) described a scanning microscope, in which a fine electron beam is caused to explore the object point by point, the transmitted (or reflected) intensity being collected in an electron multiplier the output of which modulates the intensity of the synchronously deflected spot of a display tube. As there are no lenses beyond the object, the energy loss of the scattered beam leads to no chromatic aberration, and the resolution is limited only by the size of the exploring probe. In principle this can be reduced to the order of Angstrom units by high demagnification of the primary beam, but the intensity becomes impracticably small because of lens aberrations. So far a spot size of some 500 A. has been obtained with a beam current of 5×10^{-12} amp., giving images of this resolution both in transmission and by reflexion. The new instrument is a great advance in both resolution and speed of operation on earlier attempts to use the scanning principle[7]. It promises better ultimate results than the simple reflexion method, both in resolution and in lack of damage to the specimen. As a much greater proportion of the scattered beam is utilized and object points are illuminated successively, not simultaneously, the rate of energy transfer is very low. On the other hand, the reflexion method can be practised by a simple adaptation to an existing microscope, with no extra electrical complications.



4. Cleavage surface of zinc single crystal, showing twins (*cd*, *ef*, *op*) and dust par-les (*a b*); $\theta_1 = 5°$. Transverse magnification × 1,800. (Physics and Chemistry of Surfaces Laboratory, Cambridge)

Both methods open up new prospects of high-resolution microscopy, especially for metallurgy, and the full exploration of their potentialities will be awaited with great interest. V. E. COSSLETT

CYTOCHEMICAL AND CYTOLOGICAL STUDIES OF DRUG ACTION*

By PROF. J. F. DANIELLI
King's College, London, W.C.2

THE majority of the actions of drugs are exercised at the cellular or lower levels of organization of living matter. As our knowledge of cell physiology is extremely limited, so likewise must our knowledge of drug action be limited. But the present rapid expansion of our knowledge of cellular activities ensures that each year new possibilities become available to the student of drug action. In this article some recent cytological and cytochemical studies of drug action will be briefly discussed.

The mitotic poisons have particularly attracted the attention of cytologists. These substances are of interest from many points of view—in the analysis of nuclear behaviour, for the production of mutant and polyploid strains, for the chemotherapy of tumours, etc. Only in the past few years has it been sufficiently realized that mitosis is not a unitary process, but consists of a considerable number of phenomena which normally, but not necessarily, occur in succession. Among the processes involved or essential for mitosis are duplication of genes and of chromosomes (involving syntheses of specific nucleic acids and proteins), the disappearance and reappearance of nucleoli, spiralization and despiralization of chromosomes, division of the centrosome, breakdown of the nuclear membrane and its reformation, formation and disappearance of the spindle and asters, formation of the equatorial plate of chromosomes and the separation of daughter chromosomes: all this is normally succeeded by cytoplasmic division, which is in itself a separate and complicated group of phenomena. Careful studies by cytologists have shown that substances which interfere with nuclear division may act upon almost all, if not quite all, the individual features of division, with a highly variable degree of specificity. At one extreme, Ostergren[1] and his colleagues have shown that almost any organic substance, if present in a concentration of the order of one-fifth to one-tenth of the level required to exercise a non-specific narcosis, will interfere with mitosis by causing (for example) chromosomes to adhere to one another to an abnormal extent. This is a quite non-specific action. At the other extreme, substances such as colchicine, podophyllotoxin and aminopterin will interfere with some mitotic phenomena at a concentration greatly below the narcotic level[2]. This can be a very specific action, exercised mainly on one or a few of the phases of mitosis. Between these two extremes lie substances which show some degree of specific action. Cytochemical studies so far have indicated only that, when a given cytological abnormality is produced, it has a characteristic cytochemistry, irrespective of the agency which produced the abnormality.

---

* Based on a public lecture delivered at University College, London, on February 22.

Many attempts have been made to produce a theory of action of mitotic poisons, for example, that they react with SH groups of proteins, or involve cross-linking of protein or nucleic acid molecules by bifunctional compounds. But no theory has so far been proposed which has commanded any considerable measure of support. It seems improbable that all mitotic poisons work by the same mechanism, and experience in other fields suggests that different groups of mitotic poisons have different initial modes of reaction with cells, and that the resemblances that are seen in the effect of these substances result from a funnelling process. It is common experience in cell physiology to find that if a cell is capable of a given activity, then many unrelated agents will elicit this activity, that is, cells appear to be organized so that a diversity of agents will produce a limited number of responses[3]. In the case of mitotic abnormalities, not only are similar abnormalities produced by X-rays and by many different families of chemical substances, but also by malnutrition and even by simple exposure to hypotonic or hypertonic media. Thus mitotic abnormalities are produced by a wide variety of unrelated agents which produce their end-effects on a complicated sequence of processes.

This phenomenon of the 'funnelling in' of the action of agents to give similar mitotic abnormalities makes it appear probable that we shall only achieve understanding of the mode of action of mitotic poisons by the highly detailed investigation of individual groups of closely related substances. The beginning of such an analysis, on the cytological level, has been made by a number of workers, particularly Ford[4], Revell[5] and Koller[6]. Their work has shown that in the case of the Walker rat tumour and of bean root tips the sensitivity of a cell depends upon its position in the mitotic cycle. Thus the number of chromosome breaks in bean root tips which is produced by a given dosage of X-rays is minimal just after mitosis, reaching a maximum if irradiation occurs shortly before mitosis. But with a nitrogen mustard, and also with a diepoxide, exactly the reverse condition was found: sensitivity was greatest immediately after mitosis, reaching a minimum just before mitosis. This difference is emphasized by the fact that, whereas anoxia and presence of SH compounds affords some degree of protection against the action of X-rays, no such protection occurs against the action of a nitrogen mustard. It thus seems certain that, although X-ray and these two chemical substances produce simila mitotic abnormalities, their modes of action must b quite different. Furthermore, colchicine and amin opterin will produce a maximal effect if applied jus before mitosis: consequently these two substance must produce spindle abnormalities by a proces quite different from that involved in the action of nitrogen mustard[2].

A more intimate knowledge of the mode of actio of some mitotic poisons might be obtained by cytc chemical methods. In principle the site of action o for example, a nitrogen mustard, could be determine either by auto-radiography of a mustard containin a radioisotope, or by the development of a colou reaction for a mustard[7]. So far no results have bee recorded of auto-radiographic studies. But attempt have been made by Bell and Danielli to determin the site of action of an aromatic nitrogen mustar synthesized by Ross. It was found that there was n evidence of specific attack of the mustard on an particular cell site: the action is diffuse. This cor clusion is supported by the results of Ord and Daniel using the technique of nuclear transfer. By thi technique it was shown that an exposure to a nitroge mustard which is just lethal to cytoplasm is also jus lethal to the nucleus. There was no sharp selectivity c the nitrogen mustard for either nucleus or cytoplasm

Although the detailed investigation of the cytc logical and cytochemical effects has not revealed th mode of action of any one mitotic poison, neverthele the work of Koller and others has profoundly ir fluenced our attitude towards these substances a chemotherapeutic agents. For it has been show that, although almost all the compounds which hav a value as chemotherapeutic agents for tumours cau chromosome breaks and mutations, nevertheless it improbable that these beneficial effects are due t chromosome breaks, etc. What then is the significanc of this correlation of therapeutic action with abilit to cause chromosome breakage and mutation Perhaps the answer is to be found in the fact th the tissues which are most sensitive to mitot poisons include tumours, lymphocytes, the bor marrow, the intestinal epithelium; that is, tho systems which are most vigorously engaged in tl synthesis of proteins and nucleic acids. The pr duction of chromosome breaks and mutations ma be viewed as an interference with the synthesis specific proteins and nucleic acids; and so tl correlation between therapeutic effect and ability produce chromosome breaks and mutations m simply indicate that in all cases the agent is actin directly or indirectly, upon the systems synthesizi specific proteins and nucleic acids. If this is so, the will be great difficulty in finding a mitotic pois which is more effective as a therapeutic agent th those which are already known. The reason for tl is that, so long as the agent which is sought is o which is selective in its action upon nucleic acid protein synthesis, the agent must be no mo destructive to tumour cells than to those vit systems of the body which are also normally engag in the rapid synthesis of proteins and nucleic aci To escape from this dilemma a new approach to tl type of drug is essential.

A possibility which appears promising is to desi a drug which, while still a mitotic poison, is depende for its action upon another cell variable, that is, t requirement for whose action is based not one but on two cell variables. The larger the numb of cell variables concerned in determining a drug action, the more selective will that drug be. Two additional variables which will be considered here are (i) enzymic constitution, and (ii) secretory activity.

Greenstein has pointed out that each cellular species, including tumour cells, displays a characteristic spectrum of enzymic activities[8]. There are enormous variations in the concentrations of particular enzymes in particular cell species. If, therefore, we take a mitotic poison, and inactivate it by adding to it another group, we make that substance relatively inert except to those cells which have a high concentration of the enzyme which can remove the inactivating group. In fact, we endow the mitotic poison with the equivalent of a proximity fuse, which is touched off only by a particular enzyme[3]. Instead of having a mitotic poison which is specific only for cells which are rapidly synthesizing nucleic acids and proteins, we should have a poison which should act only on those cells which are rapidly synthesizing proteins and nucleic acids, *and* which also contain a high concentration of a particular enzyme.

Designing a drug to fit into certain cellular secretory patterns also holds some promise. It is known that cells may be extremely selective in the types of molecules which are concentrated within their plasma membranes. But detailed information is much more scanty than is the case for the distribution of enzymes, and consequently the exploitation of this variable is likely to be less rewarding at the present time.

It is perhaps important to point out that these two variables have been exploited in the past—inadvertently. The reason why neoarsphenamine is an effective drug for treatment of certain infections of the central nervous system is that (*a*) as a result of having a particular type of distribution of polar groups, it is caught up by the secretory cells of the blood–brain barrier and transferred from the blood into the brain, and (*b*) once in the brain it is reduced to liberate active arsenoxides from a hitherto inactive compound.

Another stimulating example of the use of cytochemical techniques is the work recently carried out at King's College by P. H. Staple[9] on the use of diphenylhydantoin. This drug is in common use for the treatment of epileptics. It acts as an anticonvulsant, without causing widespread depression of the central nervous system. But in a proportion of patients the drug causes gingival hypertrophy, which interferes with eating and is unsightly. Cytochemical studies of the hypertrophied tissue showed that connective tissue, particularly collagen, was involved. Collagen is known to be influenced by corticosteroids, and the peculiar localization of the hypertrophy and the waywardness of its incidence were suggestive of a 'stress' abnormality involving he adrenals. Consequently the adrenals of mice were examined by cytochemical methods after a period of reatment by the hydantoin. A gross lesion of the adrenals was revealed. On the hypothesis that the drug was acting directly on the adrenals, it was argued that aspirin might antagonize the undesirable side-reactions of the drug. But it was speedily found that administration of aspirin antagonizes the central effects of the drug, and precipitates convulsions.

It thus became necessary to consider the possibility hat both the central and peripheral effects of diphenylhydantoin are mediated through the adrenals, that is, that epilepsy might be caused by either (*a*) excessive secretion of cortisone, or (*b*) abnormal sensitivity of some part of the central nervous system to cortisone. Either possibility might involve a breakdown in glucose supply to part of the brain tissues. In confirmation of this line of thought, evidence has been found that cortisone and adrenocorticotropic hormone may induce epileptic convulsions in a proportion of normal patients, whereas deoxycorticosterone, which in some respects is antagonistic to cortisone, will protect epileptics against convulsions.

It is evident that, with the aid of cytological and cytochemical techniques, entirely new ground can be broken in the study of drug action and in the development of new drugs.

FIBRES, OLD AND NEW

THE primary needs of man have always been food, shelter and clothing. The first he was promised by the sweat of his brow; the second he found originally in caves and other natural formations until primitive constructive abilities and later engineering skills enabled him to build to his own design; but the third provided him at a very early stage in his development with scope for extraordinary ingenuity, especially in his discovery of the possibilities of fibres. The historical, scientific and economic consequences of this discovery were discussed at Belfast on September 5 by Section B (Chemistry) of the British Association, when Dr. Douglas W. Hill (British Cotton Industry Research Association) introduced the subject, Dr. A. J. Turner (Linen Industry Research Association) discussed "Naturally Occurring Fibres", Dr. A. R. Urquhart (Lansil, Ltd.) "Natural Polymer Fibres" and Dr. Rowland Hill (Imperial Chemical Industries, Ltd.) "Synthetic Polymer Fibres".

The origins of textile manufacture are lost in antiquity. Before history began, men had discovered the secret of twisting fibres together and interlacing the resultant yarns to produce strong and flexible coverings. So valuable did these products prove to be, not only for clothing but increasingly for all kinds of coverings and later for industrial purposes, that the world was combed for raw materials for the textile industry. Animal, vegetable and mineral products, provided they possessed the requisite fibre form, were all pressed into service, and new uses and new manufacturing methods were constantly exploited. The animal world yielded wool, horsehair, mohair and alpaca, the hair of cows, camels and the fur of rabbits, in addition to silk, both cultivated and wild. From the vegetable world came cotton, linen and flax, ramie, jute and coir, hemp, manila, sisal and phormium, and many others as major articles of commerce, as well as locally-used fibres such as those from the pineapple, from which yarns and fabrics of the finest quality have been produced.

Even paper, cut into narrow strips and twisted, has been extensively used. The mineral world yielded asbestos, the only natural fibrous mineral, and also gold, silver, copper, iron and glass, all of which can be converted to fibrous form for use in the spinning and weaving processes. The vast number of industrial commercial natural fibres now in use has been established by a struggle for survival in world markets, but the search for new ones continues vigorously.

The larger proportion of the world's textiles until quite recently was a matter of agriculture. In view of the stress which was rightly laid during the meeting on the importance of research in the production and use of the natural and synthetic polymer fibres, it is perhaps as well to appreciate that, but for research work, there would be only a minute production of the natural fibres. In fact, while it is generally realized that the man-made fibres are a consequence of man's control of physical forces, it should not be overlooked that the present abundance of natural fibres is no less dependent on man's control of biological forces. The original wild, naturally occurring fibres were mostly deficient in the qualities that would make them economically valuable to-day, and they have been improved out of all recognition by selection and breeding. Research continues to-day in greater measure than ever to produce new varieties and strains with improved yield and quality and disease resistance, while extensive agronomic experiments are directed towards improving cultivations.

It might be thought, in the light of the available natural fibres, with all their different chemical and physical characteristics, that the need for and the opportunity of successfully launching man-made counterparts would be negligible. In a world hungry for textiles, however, every possibility of increasing the total supply or widening the range of properties has been avidly seized upon. The suggestion that fibres might be produced artificially is by no means a new one. In 1664 Dr. Robert Hooke put forward the idea that suitable substances could be drawn out to produce fibres, and in 1841 a machine for spinning artificial fibres was actually demonstrated at the British Association's meeting in Manchester. Although this project came to nothing, it is significant in that it was the forerunner of the spinneret afterwards used so effectively in the rayon industry, and that the filaments demonstrated at that meeting were drawn glass, which has become one of the latest additions to the range of commercial textile fibres. The further development of artificial fibres was stimulated not by the textile industry but by the demand for filaments for use in the new electric-light bulbs. Sir Joseph Swan took out a patent in 1883 for fibres drawn from nitrocellulose which was afterwards denitrated, and these were exhibited in 1885 in their first textile form as crocheted nets. The Count de Chardonnet had also patented textile fibres drawn from nitrocellulose in the previous year, but unfortunately he did not denitrate his fibres, and the dangers which he introduced were so great that the use of his products was forbidden.

The rayon industry, as we now understand it, may be said to have started in 1891 with the discovery by Cross and Bevan that cellulose could be dissolved in a mixture of caustic soda and carbon disulphide to produce viscous solutions from which the cellulose could be readily regenerated after drawing out into fibres. From the success of the first regenerated fibre have sprung many others, including cuprammonium rayon, obtained by extruding a solution of cellulose in cuprammonium hydroxide into water; cellulose acetate after the First World War; and in more recent times, 'Ardil' from groundnut protein, alginate fibre from seaweed, 'Vicara' from zein and 'Lanital' from casein. Once again, as in the case of the natural fibres, a great hunt for spinnable materials took place, and every conceivable waste-product was tested for its possibilities for this purpose. Egg-white, feathers, silk waste, soya bean and fish have all been used to provide further weapons in the armoury of the regenerated fibres.

Two facts stand out with peculiar significance in this narrative. The first, and more obvious, is that the advances in fibre production have occurred during the past fifty years. Though the methods of manufacture changed and were continually refined, the same basic materials were used by the milliners in the fashion houses of Paris at the beginning of the twentieth century as had been used thousands of years earlier by the dressmakers in the courts of the Pharaohs.

The second and less obvious fact is that, although the advent of man-made fibres coincides with the development of scientific research, viscose rayon was a discovery of an empirical nature. It could, indeed, scarcely have been anything else, since there was at that time no understanding of the nature of fibre structure. The classical methods of organic chemistry which proved so fruitful in other directions were virtually ineffective when applied to fibres. The properties of fibres to which they owe their value for textile purposes are mechanical ones, such as strength and elasticity, and the chemists of the nineteenth century, though interested in some physical properties of materials, had not regarded mechanical properties as coming within their purview.

At the time when the production of viscose rayon was a fully developed industry, the modern theory of the structure of textile fibres was unborn. Even at the time of the development of acetate rayon, the conception of the cellulose molecule as a very large number of glucose units combined with one another by glucoside-like linkages to form a long thin chain was neither widely known nor generally accepted.

The study of synthetic linear polymers, of which the constitutions were known, provided the key to the problem of fibre structure. It introduced the conception of average molecular weight in place of the previously accepted constant molecular weight together with relationships between viscosity and average chain-length which were independent of chemical transformations.

One well-known phenomenon proved to be a considerable obstacle to the acceptance of the molecular chain theory, for, if cellulose consists only of identica glucose units identically linked, there appears to be no reason for supposing that the conditions which produced rupture of some bonds would not produce rupture of all of them. It was, however, well known that the hydrolytic action of dilute acids on cellulose ceased before complete conversion of the molecule to glucose units. Fortunately the application of X-ray studies to the problem of fibre structure provided a solution. These studies established the presence in the fibre of crystallites interspersed with amorphou regions. In the light of this evidence, the action of dilute acids on cellulose became less a matter of chemical reactivity and more a matter of accessibility, the amorphous, loosely packed, randomly arranged areas being more accessible to the acid than the highly oriented, densely packed crystallites.

The X-ray studies also offered an explanation of the strength of textile fibres and opened up a method of increasing it and of changing the chemical reactivity. According to the modern view the strength of a fibre is determined not by the strength of the glucoside link but by the secondary valencies or hydrogen bonds holding the crystals in a regular pattern; and it breaks, not by rupture of the primary valencies, but by the chains slipping past each other, with a consequent rupture of the hydrogen bonds holding the structure together. The greater the length of the chains, therefore, the longer the overlaps between them and the greater the number of lateral bonds which must be disrupted before breakage occurs. The extent of the crystallinity, it was soon learned, could be increased by mechanical means, particularly stretching, which brought about, as X-ray studies showed, a further orientation of the fibrous molecules.

The climax of the study of fibre structure was reached in the decade following 1928. In that year a long-range fundamental study was initiated in the Du Pont laboratories under the brilliant direction of Dr. W. H. Carothers, which produced in 1931 the announcement of what amounts to a specification for the production of fibres from synthetic polymers. The specification still holds, though it can now be filled in with greater detail. The proof of Carothers's views was provided by the publication in 1938 of the patents covering the production of nylon—polyhexamethylene adipamide—not only the first of the synthetic fibres but also the first fruit of the modern theory of fibre structure.

The pattern of development of both the natural and the regenerated fibres was again followed. A vast search began for synthetic polymers which could be converted to commercially valuable fibres. Nylon, therefore, has been succeeded by others, including 'Perlon', another polyamide, 'Orlon' and 'Acrilan', polyacrylic fibres, 'Vinyon', a co-polymer of vinyl chloride and acrylonitrille, 'Saran', a co-polymer of vinyl and vinylidene chlorides, and 'Terylene', polyethylene-terephthalate.

The discovery of how to use the fibres provided by Nature, by twisting them into yarns and producing from them delicate and serviceable fabrics, must rank as one of the greatest and most lasting achievements of human genius. The unravelling of the inner secrets of their structure is a further chapter in this story, no less enthralling than the earlier episodes, and proving, if proof were needed, that man has sustained his genius through the centuries.

The introduction of synthetic fibres has not meant, so far, that the older fibres have become obsolete. The rayon industry has grown from a production of 2 million lb. a year in 1900 to more than 3,500 million lb. a year in 1950. Synthetic fibres have increased from 2 million lb. a year in 1938 to 150 million lb. a year in 1950. Both are still expanding industries; both offer competition to the natural fibres; yet the use of cotton and wool has also expanded during the century, and even silk, which had a production of 38 million lb. a year in 1900, still reached a production of 36 million lb. a year in 1950, after all the vicissitudes, devastation and trade dislocation consequent upon the Second World War. The present world production of textile fibres is about 22,000 million lb. a year, and during the past decade it has shown an annual increase of about 3 per cent; of this total, the man-made fibres contribute about 15 per cent. The struggle for survival which established the commercially valuable natural fibres will ultimately decide the relative use of the natural, regenerated and synthetic fibres.

It is improbable, however, to say the least, that an ideal fibre suitable for all purposes will ever be discovered. Consider for a moment the many demands which may be made upon fibres. Apart from the fact that they must be available in very large amounts, they may be expected to exhibit strength, elasticity, resistance to abrasion, resistance to shrinkage, to soiling, to fire and to light, moisture absorbency or moisture repellence, warmth, affinity for dyestuffs, chemical reactivity or chemical inertness, and many other properties, some of them all at the same time, and some of them mutually opposing.

Moreover, progressive industrialization demands specialization in fibres as it has already done in metals and other materials. It is true that modern theory has taught us how to modify fibres to meet more exactly the demands made upon them. Rayon, for example, introduced as an apparel fibre, now finds a great outlet in tyre yarns; and nylon, renowned the world over as America's contribution to lustrous hosiery, has gone to war in parachutes, glider tow-ropes and now in bullet-proof vests. Nevertheless, there is a natural limitation to what can be accomplished with any single fibre. It is instead the variety of properties available in different fibres, either alone or in admixture with each other, which makes it possible for designers to fulfil almost any demand that they may be called upon to meet. So varied are these demands that virtually any outstanding property can be turned to advantage, whether it be the buoyancy of kapok, the drape of acetate rayon, the utility of cotton, the warmth of wool, the glamour of silk, the strength of nylon, the fire-resistance of glass or even the solubility of alginate.

On the other hand, the production of the different classes of fibres may well be governed by considerations other than their immediate apparent usefulness. Of the primary needs of man referred to at the beginning of this article, it must be accepted that food is pre-eminent, and an expanding world population, much of which is already below a reasonable subsistence-level, will call for a concerted attack on the problem of food supplies. The natural fibres are all produced in the temperate and warm regions of the world, that is, in just those regions which must be relied upon for any increase in the production of food. Regenerated protein fibres too, though now manufactured from materials unfit for consumption as food, might find that a general food shortage enforced improvements in production methods of their raw materials which would make them suitable foodstuffs for human or animal consumption. The regenerated cellulose and acetate rayons and the synthetic fibres might in such circumstances make a considerable contribution to the food situation. The manufacture of the cellulose and acetate rayons from wood pulp enables a new area to be utilized for fibre production, namely, the Arctic and sub-Arctic forest regions, in which there is no competition with food production. It might be, therefore, that the future will see a reduction in the quantity of natural fibres used, and their replacement by fibres derived from wood pulp.

The future of the synthetic fibres may be limited chiefly perhaps by the availability of raw materials and the vast investment costs of the necessary plant. How great are these costs is not generally appreciated. It is reported that, for the development of nylon, the Du Pont Company spent 45 million dollars on research, 21 million dollars on sales campaigns and 196 million dollars on plant. The new plant of Imperial Chemical Industries, Ltd., for the production of 'Terylene' is estimated to cost £10 million. It is not surprising, therefore, that the birth of a structurally new fibre of merit and distinction is a rare occurrence. The combined efforts of the great many scientific workers who during the past twenty-five years have examined thousands of possible products have led only to five classes of synthetic fibres.

Nevertheless, whatever the future relations may be between the various classes of fibres, textile manufacturers now have at their command a range from which it is possible to create products transcending all past conceptions of textile utility. In the near future, the art or, as it is now fast becoming, the science of textile production may reflect as never before our achievements in the fields of chemistry and physics.

D. W. Hill

ANTIBIOTICS IN ANIMAL NUTRITION

Within the past decade the application of antibiotics has had a profound influence on human and veterinary medicine. Recent developments show that their impact on agriculture may be equally important, and it was apposite that this year at Belfast, Sections I (Physiology) and M (Agriculture) of the British Association should discuss in joint session the place of antibiotics in animal nutrition.

In his opening remarks, Dr. S. K. Kon (National Institute for Research in Dairying) traced the steps that led to the surprising discovery of the growth-promoting effects of these drugs. It has been known for a long time that proteins of animal origin are, on the whole, biologically superior to those derived from plants; in fact, the classic concept of first- and second-class protein was based on this distinction. When later the emphasis shifted from protein as such to its component amino-acids, it became evident that something else apart from a good balance of these was responsible for the special virtue of animal sources of protein. Work with rats and poultry in the United States, especially by Hartman and Cary and Bird and his associates at Beltsville and the Zuckers of Columbia University, showed that these products carry a hitherto unrecognized growth substance which, owing to its association, came to be known as the animal protein factor. It is only fair to recall that some twenty years ago Dr. Katherine Coward, working in England in the laboratories of the Pharmaceutical Society, showed that the purification of casein deprived it of something essential for the proper development of rats on synthetic diets.

With the brilliant isolation in 1948 of the anti-pernicious anæmia factor by Rickes and his associates, of the Merck Laboratories, New York, and by Lester Smith and colleagues, at the Glaxo Laboratories, Ltd., Greenford, and its identification as a vitamin by the former workers, it soon became apparent that vitamin B_{12}, as it was called, accounted for much of the special activity of carriers of the animal protein factor. The value of vitamin B_{12} in enhancing practical rations for pigs and poultry in the United States led to a search for suitable sources, and these were found in the residues from the antibiotics industry, especially from fermentation processes in the preparation of aureomycin and streptomycin. Thus a substance at first believed to ennoble only animal tissues came to be derived mainly from activities of micro-organisms.

The crude product from *Streptomyces aureofaciens* proved better in poultry rations than an equivalent quantity of pure vitamin B_{12}. Shortly after this observation, Stokstad and Jukes, of Lederle Laboratories, announced that the superiority was due to the presence in the residue of traces of aureomycin and that the antibiotic, even by itself, promoted the growth of pigs and poultry. At first sight this unexpected effect seemed scarcely credible, and Dr. Kon confessed his initial disbelief; but confirmatory evidence soon came from numerous laboratories in the United States and from the Shinfield Dairy Institute itself, establishing that animals benefit from the addition to their diet of any one of several antibiotics, especially penicillin, aureomycin, terramycin and streptomycin. Commercial application on a large scale was not slow to follow in the United States, where antibiotics are now included in many practical rations for pigs, chicks and turkeys.

In Great Britain the use of antibiotics is governed by the Penicillin Act, 1947, and their addition to rations is for the time being prohibited. Controlled experiments are now in progress in several centres under the ægis of the Agricultural Research Council, and an official statement of policy will no doubt be made when the tests are completed. This cautious attitude is certainly well founded. To begin with, husbandry and feeds in Britain are so different from those in the United States that British workers cannot call on the wealth of American experience but must work out their own solution. In examining the problem afresh, the possible dangers of placing powerful drugs indiscriminately in the hands of farmers must be carefully considered. Their action on frank disease must be dissociated from that in promoting growth of apparently healthy stock. How the antibiotics act is still a mystery, though all indications are that it is in some way through the gut flora. Long-term effects, with the associated risk of appearance of resistant strains, must thus be faced. Finally, the value of antibiotics for ruminants and for laying birds is, to say the least, doubtful, and care must be taken that they reach only those animals they can help. Antibiotics may well become of major importance in British agriculture, but they should not be introduced without proper safeguards.

Dr. M. E. Coates (National Institute for Research in Dairying) discussed the mode of action of antibiotics. Three hypotheses to account for the growth-stimulating properties of antibiotics, when given by mouth, have been proposed: they may themselves be essential growth factors; they may alter the intestinal micro-organisms to the benefit of the host; or they may suppress some infection in the gut interfering with normal growth.

The first explanation is unlikely, since several antibiotics of different chemical constitution all have a similar growth effect; in addition, this effect is shared, though to a less extent, by sulphonamides, arsonic acids and some detergents and is, therefore, more likely to be brought about through the common antibacterial action of all these compounds.

The remaining two hypotheses were investigated in experiments, which Dr. Coates proceeded to describe. Repetition at Shinfield confirmed the original findings of Stokstad and Jukes that pure aureomycin promotes the growth of chicks, and penicillin and terramycin acted similarly. The antibiotics were effective with normal chicks and with chicks deprived of the animal protein factor. Most of the later work was done with only one antibiotic, penicillin, which was readily available in Great Britain. Assays showed that, given as the procain salt to the extent of 25 mgm./100 gm. diet, it survives in bacteriostatic concentrations as far as the lower intestine, but no consistent bacteriological differences were detected either by direct microscopy or by cultural methods between birds with or without the antibiotic.

Changes in microbial population or in its behaviour are likely to result in changes in vitamin requirements of the host chick, particularly of those vitamins of the B complex that can be synthesized by intestinal micro-organisms. Experiments with diets deficient in any one vitamin indicated that penicillin increases the chick's requirement for nicotinic acid but spares biotin, folic acid and one or more unidentified components of the complex represented in the animal protein factor. Biely, in Vancouver, found that aureomycin spares nicotinic acid, folic acid and riboflavin, but the differences between the two laboratories were probably due to differences in experimental conditions. The salient point was that these vitamin economies alone are insufficient to account for the dramatic growth response to antibiotics, particularly as it was also obtained at Shinfield with baby-chick mashes containing ample vitamins and animal protein. Comparison of these latter findings with those of workers at the Glaxo Laboratories provided a pointer to a different explanation in that chicks at Glaxo given baby-chick mashes did not respond to penicillin. The chick rooms at Shinfield had been in continuous use for poultry for at least ten years, whereas poultry had rarely been housed in the Glaxo Laboratory. In a joint experiment chicks from the same hatch and receiving the same batch of diet were divided between the old Shinfield place, a new room there that had never contained poultry, and the Glaxo Laboratories. Penicillin improved growth only in the old place. The treated chicks grew as well there as those, treated or untreated, in the other two places where penicillin had no effect. The antibiotic was, in fact, preventing a depression, rather than causing an increase in growth. Chicks from the new room showed a similar depression when birds from the old room were placed in the same cages with them. Careful examination of the birds revealed no signs of any recognizable disease, and the evidence suggested that the improved growth with penicillin in the old room resulted from a suppression of an inapparent transmissible 'infectious' condition that prevented the birds from growing optimally. Support for this view came from the work of Reyniers, of Notre Dame University, who, Dr. Coates said, obtained no response to antibiotics in his germ-free chicks.

The characteristics of the infective agent are now being studied at Shinfield by means of 'Perspex' isolation boxes, each housing two cages, in which 'infected' and 'uninfected' chicks are kept side by side. The agent can be transmitted by the whole-gut contents of 'infected' chicks, but not by those of 'uninfected'.

Dr. Coates concluded by saying that in frank disease, and in the inapparent 'infection', the beneficial effect of antibiotics on growth manifested itself both on complete diets containing sources of animal protein and on all-vegetable diets. With 'uninfected' chicks it was obvious only with the latter. Finally, with germ-free chicks, antibiotics should be ineffective whatever the diet.

Dr. W. F. J. Cuthbertson (Glaxo Laboratories, Ltd.) spoke next, on antibiotics and the animal protein factor. After outlining the steps that had led to the recognition of the animal protein factor as a complex of which vitamin B_{12} forms only one of the important constituents, he pointed out that antibiotics behave like animal foods in that they increase the growth of chicks, rats, pigs and turkeys on purely vegetable rations to a greater extent than vitamin B_{12} alone. The joint experiments with the Shinfield workers have shown that, when the growth effect is manifested with good diets containing the animal protein factor, it is due to the presence of a growth-depressant 'infection'. He has found, however, that on all-vegetable rations even 'uninfected' chicks benefited from the addition of antibiotics to their diet; the removal of the 'infection' cannot, therefore, be a complete explanation of the growth-promoting action of these drugs. The vitamin B_{12} requirements of such birds were reduced by the antibiotics. Even when the parent flock was kept on a normal diet and their 'uninfected' chicks received a vegetable ration containing ample amounts of all the known vitamins, including vitamin B_{12}, penicillin still improved growth. This effect could not be explained by a vitamin-sparing action on the known vitamins or by anti-infective activity, but indicates that the antibiotic decreases the chick's need for some unidentified essentials. In fact, the addition of heat-dried liver to the all-vegetable diet improves it only a little; but additional penicillin has a marked effect, whereas the opposite was true with freeze-dried liver, indicating that penicillin has spared a heat-labile unidentified growth essential.

A possible explanation of these findings is that antibiotics control the activities of the gut micro-organisms by encouraging those that synthesize growth factors and removing those that destroy them. Dr. Cuthbertson said that one could further speculate that the growth-depressant 'infection' demonstrated in chicks may act by increasing destruction of growth factors in the gut. Should this prove true, the addition of these factors might increase growth on rations now considered optimal but, in fact, not containing enough of certain components to allow for loss through bacterial activity.

In the discussion Mr. K. L. Robinson (Queen's University, Belfast) said that in his experiments on pigs he had obtained a marked response to antibiotics both with all-vegetable diets and with diets containing fish meal. Food utilization was also increased. Removal of the antibiotics at the mid-fattening stage produced a setback that was cured when the antibiotic was given again. Another speaker, from Dublin, said that in his experience penicillin improved the growth of pigs on diets containing maize, soya-bean meal and fish meal, but that the effect was greater when maize was replaced by wheat offals and oats. With chicks he observed improvement on all diets.

NEWS and VIEWS

Royal Society: Award of Royal Medals

H.M. THE QUEEN has been graciously pleased to approve recommendations made by the Council of the Royal Society for the award of the two Royal Medals for the current year as follows: to Sir Frederic Bartlett, for his creation of an experimental school of psychology which has established under his leadership an outstanding position recognized internationally as without superior; to Prof. C. K. Ingold, for his extensive theoretical and practical studies of the mechanism of, and the factors influencing, organic chemical reactions; and for his analysis of the structure of benzene.

Institution of Civil Engineers: Awards for 1951–52

THE Institution of Civil Engineers has announced the following awards for papers (subjects given in brackets) which were read at meetings of the Engineering Divisions of the Institution during the session 1951–52: *Telford Gold Medal*, Dr. Carlo Semenza (the most recent dams by the Società Adriatica di Elettricità (S.A.D.E.) in the eastern Alps); *Coopers Hill War Memorial Prize*, Dr. E. J. Hamlin (sewerage and sewage disposal in subtropical countries, with special reference to South Africa and Mauritius); *Telford Premiums*, A. A. Fulton (civil engineering aspects of hydro-electric development in Scotland), M. C. White (the design and construction of the new deep-water quays at Leith), R. H. MacDonald (relation between daily rainfall and flow of the River Shin) and J. T. Calvert and P. M. Amoötts jointly (some problems in the disposal of industrial effluents and domestic wastes); *Crampton Prize*, W. Storey Wilson and F. W. Sully jointly (the construction of the caisson forming the foundation to the circulation-water pump-house for the Uskmouth generating station); *Manby Premium*, Dr. B. G. Neal and Dr. P. S. Symonds jointly (the rapid calculation of the plastic collapse load for a framed structure).

Biology at Chelsea Polytechnic, London:

Dr. B. Barnes

DR. B. BARNES will retire from the headship of the Department of Biology at Chelsea Polytechnic at the end of 1952. He was born in 1888 and after service as a schoolmaster and in the First World War he graduated with first-class honours in botany from Birkbeck College, University of London, in 1922. He served for thirteen years as a demonstrator and lecturer at that College, taking his Ph.D. in 1928 and his D.Sc. in 1933. He became head of the Department of Biology at Chelsea Polytechnic in 1934 and has served with distinction in that capacity since that date. He served for a long period on the Council of the Linnean Society and was vice-president during 1937–38, 1942–44 and 1951–52. He also acted as deputy treasurer of the Society during 1942–45 and as botanical secretary during 1944–51. He was president of the British Mycological Society in 1934 and was editor of the *Transactions* of that Society for a long period. He served for thirteen years on the Scientific Committee of the Royal Horticultural Society. He has also played his part as recorder and secretary of Section K (Botany) of the British Association. Dr. Barnes has made many contributions to botanical research and will be particularly remembered for the encouragement which he has given to the large number of research students who have passed through his hands, many of whom have afterwards gained distinction; his sympathy with the part-time student is particularly notable. The Department of which he has been head has grown during his tenure of office; it embraces the subjects of botany, zoology, physiology and chiropody, and no greater tribute can be paid to him than to note that it will in future develop as three separate and fully-fledged departments.

Mr. C. C. Hentschel

MR. C. C. HENTSCHEL has been appointed to succeed Dr. B. Barnes as head of the Department of Biology; the Department will in future deal only with the subjects of botany and zoology. Mr. Hentschel, who was educated at St. Paul's School, St. Bartholomew's Medical College, Birkbeck College and King's College, London, was appointed to the staff of the Polytechnic in 1931, and has been senior lecturer in zoology for many years. He was chairman of the Preliminary Medical Board of Studies of the University of London during 1944–47 and is at present chairman of the Board of Studies in Zoology and the representative of that Board on the Faculty of Science. He is vice-president of the Linnean Society, which office he has held on two previous occasions, and is a fellow of the Zoological Society. As the part author of "Biology for Medical Students", his name is familiar to many students of biology. He has witnessed a remarkable growth in the zoological section of his department since his appointment to the Polytechnic, and in the wider capacity in which he will now act will have opportunities for furthering this development.

Dr. Mary F. Lockett

DR. MARY F. LOCKETT was appointed as from September 1, 1952, to the headship of the Department of Physiology; the Department had formerly been part of the Department of Biology. Dr. Lockett was educated at Cheltenham Ladies College, the Royal Free Hospital Medical School, and Newnham College, Cambridge. She was awarded the degrees of M.B., B.S. in 1935, M.D. in 1936, and Ph.D.(Cantab.) in 1945. After holding resident hospital appointments at several hospitals in London and in Cairo she became Beit Memorial Fellow for Medical Research at Cambridge during 1941–45 and was elected to a research fellowship at Newnham College, which she held during 1945–47, when she unfortunately had to resign owing to the illness of her parents. Dr. Lockett has held posts at University College, London, and the University of Glasgow. She is an active research worker with many publications to her credit, and will have full scope for her great ability in building up her new department at Chelsea Polytechnic.

Research Grants for the Department of Anatomy, Oxford

A GRANT of 12,000 dollars has been made by the Rockefeller Foundation to the University of Oxford for advancing the research in technical methods of microscopy which is being carried out in the Department of Human Anatomy under the direction of Dr. R. Barer. During the past few years, these studies have been concerned with optical methods which are particularly suitable for the investigation of living cells, and the Department is fortunate in possessing (through the generosity of the Nuffield Foundation) the first new Burch reflecting microscope, an instrument which is specially advantageous for ultra-violet and infra-red microspectrography. Other specialized techniques under development include various forms of phase-contrast and interference microscopy, which are now being used for a general programme concerned with the action of physical and chemical agents on living cells. Recently, new methods have been devised for the optical determination of cell mass and the regional concentration of solids within living cells. Some applications of these are likely to prove of considerable value in clinical pathology.

A grant of £1,500 a year for three years has also been made by the National Coal Board for research work to be carried out in the Department of Human Anatomy (under the direction of Dr. J. S. Weiner) in collaboration with the Medical and Rescue Personnel Departments of the Board. For some years the Medical Research Council Climatic and Working Efficiency Unit in the Department has been engaged on fundamental and applied investigations on human adaptation to climate, particularly to hot environments. It is now proposed that this work should be extended to include mining problems concerning the effect of hot and humid atmospheres on health and efficiency. This work was pioneered many years ago by the late Prof. J. S. Haldane and Prof. Neville Moss, and its development in the Department of Human Anatomy at Oxford, at Singapore and (during the Second World War) at the National Hospital, Queen Square, London, has yielded a knowledge of methods and an accumulation of data much of which is particularly applicable to mining problems. The Unit at Oxford has already played a part in the inauguration of similar work in the South African gold mines. The immediate inquiries on behalf of the National Coal Board will be concerned with the performance of rescue personnel at high temperatures and with the effect of age on the ability to withstand high temperatures.

Functions of the Ductless Glands: Fiftieth Anniversary

For the scientific investigator, the most difficult of all feats is to form a new idea in the face of prevailing dogma. At the end of the nineteenth century the body was regarded as a collection of organs co-ordinated and integrated by the nervous system, and the function of individual organs was explained in terms of their nervous connexions. But it was well known that a nerveless pancreas did secrete when acid food entered the intestine. Physiologists, baffled, searched for new nervous paths. Fifty years ago, in 1902, Starling, working in University College, London, suddenly had a new idea that it must be a chemical reflex, and quickly proved this by grinding up the lining of the intestine with some weak acid, injecting it into the blood and obtaining an immediate flow of pancreatic juice. This intestinal substance was called secretin because it caused the pancreas to secrete. The functions of most endocrine glands were known; but it was not until the discovery of secretin that their role in the overall organization of the body was understood. From the example of secretin, Starling and his fellow-worker, Bayliss, postulated that the higher animals possess, in addition to the nervous system, a second co-ordinating and integrating system: substances formed in one organ circulate in the blood and regulate the function of another organ or site. To these they gave the name 'hormone' (to excite), and said that, when this word was used, the attribute of messenger should be understood. This idea of a blood-borne regulation of normal body functions has proved to be one of the most fruitful in physiology, and to-day, with the advent of cortisone and adrenocorticotropic hormone, may be ready to give us a new concept of disease.

Colonial Research and Development

The debate on the Queen's Speech in the House of Commons on November 7 was concerned with Colonial affairs; but attention was focused on the situation in Kenya, and, except in Mr. Bernard Braine's speech, Colonial research received no attention. Mr. Braine, in directing attention to the importance of Colonial development, stressed particularly the urgent need for improved transport and more knowledge about the Colonies and their human and physical resources. In this connexion he referred to some achievements in Colonial research and in particular to the work of the Colonial Products Research Council. Sir Leslie Plummer supported Mr. Braine's remarks on the importance of research, particularly agricultural research. Mr. Braine pleaded for early clarification of the present uncertainty arising from the expiry in March 1956 of the Acts under which the Colonial Development and Welfare Schemes are financed. The Colonial Research Council has already pointed out in its current report that uncertainty is making the planning of long-term research impossible and hindering the recruiting of research workers for the Colonial territories. Nevertheless, no comment on this matter was made when the Under-Secretary of State for Commonwealth Relations replied on the debate.

Laterite and Lateritic Soils

In Technical Communication No. 47 of the Commonwealth Bureau of Soil Science, entitled "Laterite and Lateritic Soils" (pp. 51; from the Bureau, Farnham Royal; 1952; 6*s*.), J. A. Prescott and R. L. Pendleton, the distinguished authors of this publication, quote the early, lucid and authoritative descriptions given by F. Buchanan (1807) and T. J. Newbold (1844). They illustrate the strikingly cellular nature of laterite by photographs of the material when used in building, and present maps showing its wide distribution in India, Australia and Africa. Laterite occurs at shallow depth and at the surface, and the bare slag-like sheets are believed to be the exposed illuvial horizon of an ancient soil. This material has a high content of sesquioxides and is usually associated with resistant minerals and with kaolinite, which may perhaps be formed by silification of gibbsite. In discussing the mobility of sesquioxides, Prescott and Pendleton suggest that high acidity resulting from oxidation of ferrous sulphides may have a bearing on the origin of laterite. Examination of Australian laterite suggests that gallium, molybdenum, lead, vanadium and zinc are concentrated with the iron, and deficiencies of copper, manganese and phosphorus have been noted where present-day soils have developed from broken-down laterite formations; such soils are usually infertile. The red earths and red loams of the tropics are formed from a variety of rocks as well as from broken-down lateritic formations, and it is unfortunate that they have received names such as 'laterite', 'lateritic soil' or 'latosol'. Prescott and Pendleton agree with the United States Soil Survey staff that it would be better to confine the word 'laterite' to such ferruginous materials as harden on exposure and to the relicts of such materials. These relicts can be found in several of the zonal soils, but they can usually be regarded as fossil and as accidental constituents that are not relevant to classification at the categorical level of the 'great soil groups'.

The Linnean Tradition in Sweden

THAT the Linnean tradition of going far afield to collect and bring back plants, thereby extending floristic and taxonomic knowledge, is still very much alive in Sweden to-day is borne out by papers contributed to a recent number of the *Arkiv för Botanik* (1, Pt. 6; 1952). Prof. Von C. Skottsberg, of the Botanical Section of the Naturhistorischen Reichsmuseums, Stockholm, has contributed a further article on the flora of San Ambrosio, off the coast of Chile ("Weitere Beiträge zur Flora der Insel San Ambrosio (Islas Desventuradas, Chile)"), while K. H. Reichinger has written both on "Plantæ novæ syriacæ" and on the flora of Turkey from collections lodged in the Stockholm herbarium.

Trace-metal Dating of Archæological Sites

NEW chemical and physical methods of determining the age of ancient sites are continually being suggested—the fluorine method, carbon-14, and the determination of phosphatic content of the soil are some examples. In a recent number of *Science* (116; July 4, 1952), V. P. Sokoloff and G. F. Carter contribute an article entitled "Time and Trace Metals in Archæological Sites". The metals in question are copper and zinc. These two metals, as well as others, occur in soils in several different forms, both mineral and organic, and they can be determined by analysis. Actually the authors are mainly concerned with the study of various middens outside the suitability and the time-range of the carbon-14 method. It is not suggested that this is a very sensitive form of test, but it could differentiate middens a thousand years old from those of, say, Pleistocene date.

Velocity Distribution of Sporadic Meteors

A PAPER by Mary Almond, J. G. Davies and A. C. B. Lovell (*Mon. Not. Roy. Astro. Soc.*, 111, 585; 1951) gave an account of the application of the radio-echo technique to the study of the velocity distribution of sporadic meteors of magnitudes 4·5–6, and a second paper (*ibid.*, 112, 21; 1952) gives further results attained from the application to fainter sporadic meteors of magnitudes 6–7·5. The apparatus was basically similar to that previously used, but additional sensitivity was acquired by increase in transmitter power and aerial gain. Two series of experiments were carried out: apex experiments during the autumn mornings of 1950; and antapex experiments during the spring evenings of 1951. Details are given of the experiments carried out during November 8–December 14, 1950, between the hours of about 5h. and 7h. in the autumn mornings. On the assumption that the meteors were moving in random directions and at the parabolic velocity limit, J. A. Clegg worked out the velocity distribution to be expected, and it was found that there was no sign of a hyperbolic velocity component. The antapex experiments were carried out between approximately 17h. and 19h. during March 29–May 18, 1951, and the velocities measured. From the velocity distribution the same conclusion is arrived at as before, namely, that there is no sign of any hyperbolic velocity component. A very interesting feature of the curves is that the theoretical curves showing the distribution on the assumption of uniformly distributed parabolic meteors indicate much higher velocities than those derived by experiment. Not only do the results all show the absence of hyperbolic velocities, but they also indicate that a large proportion of sporadic meteors must have relatively short-period orbits. Several other matters are discussed, such as the range of magnitudes and estimates of magnitude from electron densities in the trails, and also by comparison of visual and radio echo-rates. Now that the sporadic meteors can be accepted as members of the solar system, many moving in small orbits, the whole problem of their origin may have to be considered afresh. How did these short-period particles originate, and when were they formed? It seems doubtful whether any theory at present adequately answers these questions.

Conference on Malnutrition in Tropical Africa

A CONFERENCE of nutrition experts opened on November 19, at Fajara in the Gambia, British West Africa, to examine problems of malnutrition in African mothers, infants and young children. This is essentially a conference on kwashiorkor—one of many terms used to describe certain manifestations of malnutrition in young children in tropical and sub-tropical areas, especially in Africa. Kwashiorkor is now regarded as being associated with a deficiency of protein in the diet. The conference is being held under the auspices of the Commission for Technical Co-operation in Africa South of the Sahara. Delegates from the Governments of Belgium, France, Portugal, Southern Rhodesia, the Union of South Africa, the United Kingdom and African territories are to attend. There will also be observers from the Food and Agriculture Organization, the World Health Organization, the U.N. International Children's Emergency Fund and the International Children's Centre. The United Kingdom delegation includes Profs. B. S. Platt and A. A. Moncrieff from London and experts from the West, East and Central African territories.

Survey of Applied Mathematics in the United States

THE United States National Academy of Sciences, under contract by the National Science Foundation, is to make a broad survey of research and training in applied mathematics in the United States. The survey, to be carried out with the co-operation of the Office of Naval Research, the Office of Ordnance Research of the Army, and the Office of Scientific Research of the Air Force, is expected to take one year, and Dr. F. Joachim Weyl, head of the Mathematics Branch, Office of Naval Research, has been loaned to carry out the work with the advice of a committee selected by the Division of Mathematics of the National Research Council. The survey group will seek to determine the nature and extent of research in applied mathematics being carried out by government organizations, universities and industry, and will also report on the training and teaching in the subject, with an indication of the areas which are not receiving adequate support. As part of the study, a conference on training and research needs in applied mathematics will be held during the spring of 1953 to consider the findings of the survey and to examine the future of research and teaching in this field. In general, this survey will be on the lines of that on physiology being carried out by the American Physiological Society, also under contract by the National Science Foundation (see *Nature*, August 16, p. 268).

UNIVERSITIES AND UNIVERSITY COLLEGES IN GREAT BRITAIN

FOR its publication, "Returns from Universities and University Colleges in receipt of Treasury Grant for the Academic Year 1950–51"*, the University Grants Committee has continued the small format introduced last year. While the record number of students of the previous year was not attained, the decrease was only slight—85,314 instead of 85,421—and the proportion of assisted students also remained high (72·5 per cent compared with 72·8 per cent during 1949–50 and 73·7 per cent during 1948–49); the dependence on Parliamentary grants again increased and now represents 64·9 per cent of the recurrent income, 16·6 per cent coming from fees (compared with 17·7 per cent during 1949–50), 5·5 per cent from endowments and 4·3 per cent from grants from local authorities, as against 5·7 per cent and 4·6 per cent, respectively, during 1949–50. The ratio of staff to students again increased, the full-time teaching staff being now 8,603 compared with 7,930 during 1949–50. Although the number of professors increased by 48 and of readers, assistant professors and independent lecturers by 62, the increase was mainly in the grades of lecturers (360), assistant lecturers and demonstrators (83) or other grades (120). Separate figures are now given for the Colleges and Schools of the University of London for full-time staffs, income and expenditure and libraries.

Of the full-time students, 67,743 were reading for a first degree, 6,244 for a diploma and 11,327, together with 4,158 of the 16,698 part-time students, were engaged in research or other advanced work; 64,180 full-time students were in England, 5,133 in Wales and 16,001 in Scotland, the decrease in Scotland thus offsetting an increase of 776 men and 247 women in England; in Wales there were 216 fewer men but 65 more women. Of the total, 15,098 were at Oxford and Cambridge, 18,412 at London and 30,670 at other English universities and colleges. Only at Bristol and Liverpool were there increases of more than a hundred students. The total for London colleges and schools increased by 913. Elsewhere there were decreases or slight increases. The North Staffordshire University College appears in the returns for the first time. The proportion of full-time students residing in colleges and halls of residence increased to 24·3 per cent, but is still less than in 1938–39 (25·1 per cent), although the number in residence is greater (20,732 compared with 12,555). The proportion of women in residence is still nearly double that of men (38·9 per cent compared with 20 per cent); 39·1 per cent of full-time students were in lodgings and 36·6 per cent at home, compared with 33·2 and 41·7 per cent, respectively, before the War. There was a further slight increase in overseas students compared with 1949–50: 3,657 full-time and 1,628 part-time students came from within the British Commonwealth and 2,902 full-time and 1,290 part-time students from foreign countries. Of the 22,223 students admitted for the first time in 1950–51 (a decrease of 2,108 on 1949–50), 20,292 were reading for a first degree and 1,931 for a diploma, and, of those reading for a first degree, 1,836 were less than eighteen years of age and 11,656 were nineteen or more.

Although the distribution of full-time students did not differ significantly from that during 1949–50, some of the changes in numbers are noteworthy. Arts students represented 43·1 per cent of the total; those in pure science 20·1, in medicine 16·6, in technology 12·4, in dentistry 3·4, in agriculture 3·1, and in veterinary science 1·3 per cent. Of the full-time advanced students, 24·9 per cent were working for a diploma and, of the remainder, 38·8 were in arts, 34·0 in pure science, 11·9 in medicine and dentistry, 11·8 in technology, and 3·3 per cent in agriculture. While the number of full-time students in arts decreased by 455 to 37,243 and those in science increased by 251 to 17,168, there was a decrease of 342 in the students of technology. In spite of the slight increase of 54 in advanced students of technology, there is no evidence in these returns of any response to the call for more university-trained technologists sounded so urgently more than two years ago. Medical students were almost stationary at 14,201, and students in agriculture decreased by 167 to 2,606. An increase of 391 in veterinary science students was due to the incorporation in the University of London of the Royal Veterinary College with 380 students. Of the full-time students, 37,714 out of 49,999 men and 9,627 out of 14,181 women in England were receiving assistance in the way of scholarships, exhibitions or other awards from public or private funds: for Wales, the corresponding figures are 3,314 out of 3,822 men and 1,095 out of 1,311 women; and for Scotland, 8,144 out of 12,010 men and 1,950 out of 3,991 women. The percentage of assisted students in England ranged from 77·9 per cent in the provincial universities, to 65·9 per cent in the University of London; Oxford and Cambridge with 75·7 and 74·3 per cent, respectively, thus came between the two. Of the 65,831 full-time men students, 37·2 per cent were in arts, 21·1 per cent in pure science and 15·8 per cent in technology; for the 19,483 women students, the corresponding figures are 63·0, 17·0, 15·1 and 1 per cent. Medicine and dentistry claimed 44·6 per cent of the part-time advanced students, arts 30·4, technology 9·6 and pure science 8·7 per cent, compared with 45·1, 32·8, 10·8 and 10·8 per cent, respectively, in 1949–50.

The recurrent income of the universities and university colleges of Great Britain increased by £2,258,388 to £24,268,123, of which £15,767,002 was from parliamentary grants, £4,022,459 from fees, £1,329,916 from endowments and £1,040,037 from grants from local authorities. Of the total income from public funds of £16,807,039 and £7,461,084 from other sources, the University of London received £5,075,985 from public and £2,070,651 from other sources; the University of Cambridge similarly received £1,043,657 and £1,080,845; for Oxford the corresponding figures are £945,830 and £729,499; for Manchester, £912,718 and £277,390; for Durham, £720,392 and £315,985; for Birmingham, £724,752 and £271,994; for Bristol, £633,976 and £209,369; for Leeds, £700,876 and £245,261; and for Liverpool, £665,317 and £246,085. No other English university or university college, except Sheffield, with £607,415, had an income exceeding half a million pounds, though three universities in Scotland exceeded this figure: Aberdeen, with £404,450 from public and £134,337 from other sources; Edinburgh, with £738,037 and £345,198; and Glasgow, with £835,650 and £361,388, respectively. The University of Wales, including the Welsh National School of Medicine, received £847,960 from public funds and £327,164 from other sources.

---

* University Grants Committee: Returns from Universities and University Colleges in receipt of Treasury Grant, Academic Year 1950–1951. (Cmd. 8638.) Pp. 44. (London: H.M. Stationery Office, 1952.) 2s. net.

Of the total expenditure of £24,269,862, an increase of £2,501,952 on the previous year, administration accounted for 8·7 per cent, departmental maintenance 69·7, maintenance of premises 11·1, and miscellaneous expenditure 9·4 per cent. Capital expenditure met from reserves amounted to £254,274 and allocation to reserves, £236,707; for 1949–50, these figures were £472,327 and £270,993, respectively. Departmental maintenance included salaries of teaching and research staffs and payments for superannuation, the running costs of laboratories, lecture rooms, libraries and museums, and the supply of materials, apparatus, books, specimens, etc. Salaries and superannuation amounted to £11,895,971, an increase of £1,349,625 on the previous year; this represents 49·1 per cent of the total expenditure, compared with 48·4 per cent in 1949–50 and an 8·5 per cent increase in full-time staff.

Library expenditure, excluding general maintenance of library buildings, rates, heat, light, repairs, etc., amounted to £891,385 compared with £788,402 in 1949–50, the percentage of total university expenditure remaining 3·7 per cent. Of this total, £473,087 was for salaries and wages, £197,062 on account of books and £103,305 on periodicals. The University of Oxford spent £32,095 on books, and Cambridge £10,102, while a total of £51,025 (including £7,027 on the Central Library, £5,678 at the London School of Economics and £5,006 at University College) was expended for this purpose in the colleges and schools of the University of London. Nine other universities, Birmingham (£5,102), Bristol (£5,467), Leeds (£6,638), Liverpool (£8,111), Manchester (£9,092), Aberdeen (£6,995), Edinburgh (£9,648), Glasgow (£8,933) and St. Andrews (£5,307), spent £5,000 or more on books, but only London (£30,496), Cambridge (£7,542), Glasgow (£7,263), Manchester (£5,228) and Oxford (£5,175) spent a like sum on periodicals.

While these returns show that university expansion in Britain has now been halted and afford signs, as in the increasing ratio of staff to students and the slight decrease in the proportion of art students, that the universities are already adjusting themselves to current requirements and seeking to maintain or raise standards, they also contain evidence of the vulnerability of such standards to extraneous pressure with the growing dependence of the universities upon State assistance. That in itself supports the contention of the Select Committee on Estimates in a recent report regarding the desirability of giving the fullest possible information to Parliament concerning the expenditure of the grant-in-aid of universities and colleges. A Treasury Memorandum included in the Eleventh Report from the Select Committee on Estimates for the Session 1951–52 (No. 289. London: H.M.S.O. 9*d*. net) accepts the recommendation of the Estimates Committee that a note should be inserted in the estimates reconciling the amount of the quinquennial grant proposed for the academic year with the total figure of recurrent grant shown in the estimates for the financial year, but the Treasury does not consider that the estimates are the most convenient vehicle for giving information to Parliament on changes in recurrent grants. The Treasury proposes to consider the best way of making any specific changes known to Parliament, but rejects the Estimates Committee's further recommendation that the Comptroller and Auditor-General should have the right to inspect the books and accounts of universities in respect of non-recurrent grants for capital development. The Treasury considers that the existing audit of university accounts already ensures that the grant is used for the purpose for which it is intended. The detailed scrutiny of expenditure on the design and equipment of buildings inevitably raises questions of academic policy, and in the Treasury view goes far beyond the broad lines on which control should be exercised if academic freedom is to be unimpaired. The Treasury believes that such scrutiny is best left to the University Grants Committee, and it is satisfied that this Committee, with the help of its own works and buildings sub-committee and of the Ministry of Works, scrutinizes all plans for which aid is sought and requires the universities to accept the lowest tender for their work unless good reason can be shown to the contrary.

The Treasury's attitude on this point is evidence of how firmly entrenched in Great Britain is the desire to safeguard academic freedom; but the universities are now too vulnerable to external conditions for the position to be regarded with complacency. The Treasury memorandum indicates that in accordance with a further recommendation of the Estimates Committee the terms of reference of the University Grants Committee will be revised to remove the obligation to collect, examine and disseminate information on university education abroad. Approval is also expressed of the recommendation regarding continuity in the senior full-time posts of the University Grants Committee.

ELECTRICAL ENGINEERING IN BRITAIN

THE inaugural address of Colonel H. B. Leeson, on taking office as president of the Institution of Electrical Engineers, was delivered on October 9, his subject being "Electricity and Current Affairs". The relationship of the electrical industry to the economic position and prospects of Great Britain was the central theme of the address, which presented not only a detailed picture of the situation of the industry in question, but also set this in perspective in its world background. "For generations," said Colonel Leeson, "cotton and coal have been the staple of our overseas trade; engineering is the staple of the future." In 1951 roughly 39 per cent, or just over £1,000 million, of the value of the exports of all kinds from Britain represented engineering products, and, of this, £189 million came from the electrical industry.

In tracing the growth of the industry during the past fifty years, Colonel Leeson pointed out that the value of the output of the electrical manufacturers, which in 1907 was £14 million, had been estimated for the year 1951 at £700 million and, in that year, nearly six hundred thousand people were employed. Although the electrical industry thus already plays a substantial part in the country's economy, it is destined to play a greater one in the future, and the further expansion of the industry must be considered in relation to the general pattern of the national economy. The drive to balance Britain's overseas account by increased exports requires a very large expansion in the volume of engineering exports. Dealing with the difficulties besetting the achievement of this increase in exports, Colonel Leeson said, "The shortage of coal, our only natural resource, is obviously the major cause of our present instability. Of equal significance is the fall in human effort—in its broadest sense of every form of human endeavour. Typical of the causes of this falling off in human effort are the effects of shorter normal hours of work, the longer time spent in education and training coupled with National Service, and the changing structure of the population. These together have brought about shortages in every direction, such as in food, materials, houses, fuel, power, transport and production generally. All these factors in turn have induced alternating notching up of costs and wages without lasting benefit, unless it be to our foreign competitors; but with lower standards of life for many. The factors are so interlinked in their cumulative effects that it is difficult to know which is cause and which is effect".

There is, of course, a correlation between the activity of the manufacturing industries and the consumption of electricity by the nation, and it is here that the position compares very unfavourably with that of the United States, where the electrical power used per worker is nearly 2½ times that in Britain. The urgent need for the installation of more generating plant is, of course, only too evident in the load shedding which has become customary in recent years. The attainment in Britain of a yearly rate of plant installation of 2,000 MW. is imperative, and a capital investment policy covering this rate of installation is an inescapable economic necessity.

The four basic needs for economic recovery and development in Great Britain are, in Colonel Leeson's opinion, more human effort (that is, more man-hours of work); greater production of the basic commodities such as food, coal, metals, chemicals and other essential materials; more fuel and power for industry and the home; and more capital (that is, greater savings by government, industry and individuals). "We are facing," he said, "a choice and a challenge. Are we, as individuals and a nation, content to accept with complacency the relentless trend of current affairs towards lower standards of living, or alternatively, do we take up the challenge this represents, and by courage and the exertion of more strenuous individual effort on things that really matter, change the trend towards recovery and better times ?"

A considerable part of the address was devoted to reviewing the growth of employment in the electrical industry in its various branches, and Colonel Leeson gave interesting data on the distribution of professional engineers as represented by membership of the Institution of Electrical Engineers in the major subdivisions of the industry. The total number of people employed in the three main branches of the industry, namely, manufacture, electricity supply and electrical contracting, was, in 1951, nearly 846,000. Roughly 70 per cent of this total were employed in manufacture, 22 per cent in supply, and the remaining 8 per cent in contracting. The membership of the Institution of Electrical Engineers, exclusive of students, numbers 31,000, and an analysis of the percentage of this membership by occupation is as follows: manufacture, 29·8; government services, consulting engineers and others, 22·6; electricity supply, 20·6; communications, 10·0; research, education and training, 9·9; and installation and maintenance, 7·1. 18 per cent of the Institution's members are serving overseas.

The education and training of all classes of personnel in the industry are, in these days, matters of exceptional importance. The direct interest of the Institution of Electrical Engineers is by its charter limited to the professional engineer; but the Institution does concern itself with the improvement of facilities for technicians and craftsmen, and it co-operates with the British Electrical and Allied Manufacturers' Association and the Radio Industries Council to that end. Colonel Leeson emphasized the close partnership in which industry, technical colleges and universities are associated in this matter of the education and training of engineers, and he urged the recognition, in relation to professional engineers, of valuable features in industry-based 'sandwich' and part-time courses which are complementary to the full-time courses of universities and technical colleges.

The problem of the needed expansion of higher technological education can, in Colonel Leeson's opinion, best be tackled by the selection, on a regional basis, of a few of the existing major technical colleges for expansion and development. These should enjoy academic freedom under a self-governing representative administration and be free from any direct control by the local education authority. "The first essential to this objective is the setting up of a small body (including a few men of high academic and professional status) under the ægis of the Government with the necessary finance and authority to select and guide the chosen colleges in consultation with professional bodies, learned societies, and industry. It would be the duty of every section of the industry to provide facilities for additional and improved training matched to the higher standard of education—a duty rich in its own economic reward."

PLASTICITY OF MATERIALS

A CONFERENCE on plasticity, arranged by the British Society of Rheology, was held in the University of Southampton during September 25–27.

The diverse nature of the problems encountered in flow technology, problems which still lack a fundamental treatment, was strongly evidenced in the discussions which arose on the papers presented. In spite of their diversity, however, it is remarkable how many of these problems derive from the basic problem of test instrumentation. The momentum of rheological inquiry is still sustained, in the main, by those immediately concerned with the behaviour of real commercial materials, working with instruments designed to give some rapid index from which the relevant property can be deduced. These instruments have been evolved in turn from those developed in more fundamental laboratories where the properties of plastic materials made classical viscometry meaningless. This necessary departure in experimental design was, unfortunately, not accompanied by an equivalent development in theoretical treatment, and the situation has become gradually worse as instruments involving more complex stress-systems have been produced on grounds of general utility. The whole line of inquiry, from that of pure research on simple systems and idealized models to that of the actual behaviour of industrial products under conditions of use, is one which can profit from the experience of those working on other parts of the line. Disagreement still exists, often on quite basic concepts; but the general process of unification, by theory and experiment, continues.

Instrument design, the difficulties of assessing standards, reconciliation of the results of different test methods—such questions as these are of primary concern to the applied rheologist. Dr. J. R. Scott (British Rubber Manufacturers' Research Association) made it plain that no single plastimeter can meet all the requirements of the rubber industry. Either, as in the rotation-type, the shear-rate is limited, and problems of slip at the containing surfaces arise; or else, as in the Williams press-type, while simple repetitive testing can give reproducible results, the system does not appear to be one which can assist the more fundamental approach to the subject. This problem of widening the scope of industrial instruments has been faced by Mr. G. E. Bessey and Mr. K. A. Lammiman (British Whiting Federation Research Council), who described an apparatus, ingeniously adapted to a lathe bed, which can test at constant rates of extension or compression, recording load and extension on a drum. The grip problem in the extension tests is overcome by extending a specially formed closed loop of the material. The machine can also be adapted for rotation tests, recording the stress against the rate of shear, and can handle material of a wide consistency. The results are of striking reproducibility—a rare quality in plastic testing.

Data derived from such instruments are still difficult to relate significantly to other measured quantities. This aspect of interpretation of data was treated by Mr. E. B. Atkinson (*BX*-Plastics, Ltd.), mainly in relation to extrusion and the problem of errors of boundary condition. The simple assumptions of extrusion analysis (those applicable to viscometers using Newtonian liquids at low rates) can all be violated, and these effects, together with the temperature gradients that arise, lead to unusual flow phenomena. The flow curves are difficult to treat theoretically; but a basis for such a treatment—and a general equation—was proposed, and this could be reconciled with an examination of the problem in terms of dynamic similarity. Such treatments are often open to criticism on *a priori* mathematical grounds, but any approach which advances the design of the processing stages will be of positive value to the plastics industries.

Interpretation, then, has its difficulties; and if an applied laboratory device can reproduce the practical conditions to such a degree that similarity can be claimed, then one stage of interpretation is directly bridged, and the problem is reduced to a true model. This, as an aspect again of rheological instrument problems, was exemplified in a paper by Dr. G. G. Meyerhof (Building Research Station, Garston), whose investigations into the behaviour of clay blocks when compressed between plates of various shape are direct analogies of the building problems of structures where the foundations (or footings) form the upper plate, and the surface of the bed below the clay forms the lower. The yield pressure of such blocks increases rapidly with the adhesion of the material to the plates, and also with decreasing block-thickness. The results are in accord with the theoretical estimates of the yield pressure, and with the assumed mechanism of failure. The unusual occurrence of a gas-holder breaking its back enabled a field investigation to be carried out, and, when the formation of the bed below the clay was traced, the results (treated according to the foregoing theory) provided a stress distribution which beautifully accounted for the result of this impressive large-scale experiment. Mr. P. Mason (Building Research Station, Garston) provided further evidence of progress in establishing the behaviour of building materials. A compression test, of a type originally suggested by Roller, was applied to various plaster mixes, and the extraction of one index—namely, the slope of the experimental line (a log–log plot of empirical quantities which approximate to stress and strain)—provided a grading the sequence of which agreed exactly with that which field-workers, on the basis of experience, accorded to the materials.

A more fundamental instrument-technique was described by Dr. W. W. Barkas and Mr. G. N. Christensen (Faculty of Technology, University of Manchester). This has been developed for a study of the behaviour of wood fibre – water assemblies, similar to those used in the manufacture of paper. These assemblies are formed as small cylinders, placed on a sintered-glass plate and connected by wet contact to one arm of a manometer. Changes in the manometer pressure effectively vary the hydrostatic pressure applied to the assembly, and hence stress – strain studies may be made. As the stiffness of the fibres, and the size of the capillaries in such an assembly, effectively control the type of paper produced in the industrial processes, such results have direct applied importance.

Some problems arising in the choice of materials for aircraft purposes were discussed by Dr. E. W. J. Mardles (Royal Aircraft Establishment, Farnborough). Temperature specifications for such materials as greases are severe, a working range being demanded from conditions of high-altitude cold to those of local engine heat. The required properties of lubricants may be masked by effects which are functions of the instrument—surface tension effects, for example, giving rise to an apparent plasticity. The properties of certain gels are also of importance in aircraft research (cellulose acetate, for example), and the time-dependent properties of such materials were surveyed.

The conference opened with two papers concerned with the fundamental interpretation of plastic flow phenomena. Dr. A. J. Kennedy (Royal Institution, London) reviewed the experimental information available on the mechanisms involved in the creep of polycrystalline metals, and, taking such evidence together with that provided by a wide range of non-metallic materials characterized by a strength – weakness structure (long-chain compounds; mixes and aggregates of various kinds), suggested that the phenomenon of transient creep is an outcome of fairly simple statistical considerations, resulting in parabolæ with time powers which fall very closely about that of the Andrade one-third power. The behaviour of a macroscopic mechanical model was reported: this approximates to the kind of curve exhibited by practical materials. Translation into physical terms is difficult, but the physics of a system which would fulfil the requirements was outlined, and this has interesting analogies with the question of the representation of voters in a two-party electoral system.

Mr. A. Graham (National Gas Turbine Establishment) approached the representation of creep data from the same general point of view, namely, that the striking fact emerging from plasticity results is that different materials behave so similarly. Using observations on a heat-resistant alloy at high temperatures, attempts were made to find an equation capable of general application. By a process of trial and error, an equation was developed from those of Nutting and Boltzmann which can be shown to be a special case of the fractional differential equation of Scott-Blair. This equation is capable of successfully embodying the four variables—strain, stress, time and temperature—and is able to fit the various types of creep curve encountered. It is true that several constants may be involved in the more complex cases, but this is defended on the grounds that mechanisms must certainly be multiple and complex, and particularly so in the case of metals.

A. J. KENNEDY

BRITISH ELECTRONIC INSTRUMENTS IN RESEARCH AND INDUSTRY

DURING the period September 2–5 the Scientific Instrument Manufacturers' Association of Great Britain held, in London, an exhibition of electronic instruments, and associated with this was a symposium of papers describing the application of such instruments in research and in industry. This was the fourth such gathering in a series which began in 1948, the previous exhibition being in 1950, and it is now proposed to hold future symposia and exhibitions biennially.

The papers read at the symposium covered a wide field of instrumentation. At the first session a description was given of electronic control systems for large astronomical telescopes. After a discussion of the factors leading to the requirement of very accurate control of 'rate' in drives for such telescopes, there followed a review of techniques used up to the present time for achieving this purpose, culminating in the present-day forms of electronic control. A modern requirement is the ability to introduce small variations of rate, and to this end use has been made of very stable resistance-capacity tuned oscillators, either as the actual source of a reference frequency or as the means of introducing some frequency variation of a crystal-controlled source. Reference was also made to a 'photographic zenith tube', shortly to be installed in Great Britain, which will provide a new standard of absolute time determination.

An account was given at the next session of the development of resistive elements and wave-guide attenuators from a semi-conducting ceramic. In contrast to the majority of semi-conductors, pure zinc oxide has a temperature coefficient of resistivity which can be controlled between high positive and negative values; the addition of titanium dioxide makes it possible to achieve this control with commercially available materials, and to control the value of the resistivity. Small resistors, up to ten thousand ohms, and having tolerances and stability similar to grade-*B* carbon-composition resistors, have been made, and these may be used with surface temperatures up to 200° C. The material has proved to be very satisfactory for the manufacture of dummy loads to fit in metal wave-guides, as it is unaffected by rapid changes of temperature; these loads absorb microwave energy strongly and also provide a good impedance match in the wave-guide.

Research and development based on precise methods of measurement are responsible in a large degree for the progress upon which the electrical industry depends. Among other topics discussed at later sessions of the symposium were electronics in strain measurement, and electronic measurement and control for industry. In the field of strain measurement, such features as multi-channel strain-display equipment, high-speed self-balancing strain bridges, load cells, load indicators and torque meters were dealt with.

The use of ultrasonic vibrations in many diverse applications has been made possible by the development of electronic methods for the generation of such vibrations, and the final paper of the symposium was concerned with this subject. The applications for industrial purposes cover processes of emulsification and the production of finely divided suspensions; in these processes the action required is that of the dispersion of one material in another. The same principle is involved in the action of cleaning, and the use of ultrasonic techniques has been proposed both for scouring textiles and for the removal of foreign matter from solid bodies. All these effects depend upon the phenomenon of cavitation, which also makes possible the tinning of aluminium by a method involving the use of vibrations of ultrasonic frequency. Other metallurgical applications include the degassing of melts and grain refinement. Most chemical effects occur at relatively slow reaction-rates, but ultrasonic depolymerization has been widely studied: in the biological field micro-organisms have been destroyed, and claims of striking therapeutic results have been made. It appears, however, that there still remains some doubt about the practical usefulness of some of these applications, particularly in cases where high intensities of ultrasonic energy are necessary.

Many different kinds of instruments were to be seen in the exhibition which accompanied the symposium. There were examples of improved design in instruments of various types shown on earlier occasions: instruments for the accurate measurement of power, voltage, current and resistance, and also several items of equipment—signal generators, valve testers, impedance bridges, *Q*-meters—which are now the indispensable tools of the radio engineer. In addition, examples were shown of relatively new developments.

The use of direct-writing instruments for recording variable electrical quantities has until recently been confined to cases in which the rate of change was comparatively small, and direct recording was not possible when frequency components exceeding a few cycles per second occurred, the only recourse then being to photographic recording with Duddell or cathode-ray oscillographs. A new recorder has now been developed which has a moving-coil element so efficient that it may be driven by a simple valve amplifier, but which yet has sufficient restoring torque to deflect a stylus across the paper record in as little as 2·5 msec. It is thus now possible to obtain records of high-speed phenomena directly in a dry and permanent form. The suspension of the recorder is of a stiffness which makes the instrument robust enough for use in aircraft or vehicles.

With the increasing demands for maximum efficiency in temperature measurement, cold-(thermo) junction temperature control has become a factor of major importance. A new, mains-operated thermostat has been designed which overcomes the difficulties and problems of such control encountered in the past. The thermostat will stabilize the temperature of the cold junction to an extent that variations will not exceed 0·1 deg. C. There are therefore no temperature changes to note, nor is ice or liquid required. The instrument is arranged normally to be set to a temperature in the range 42°–48° C., and takes about forty-five minutes to reach stable conditions after switching on.

The needs of the chemist have not been neglected: instruments are now available which will give a continuous indication of the pH of any given liquid under examination, so that rapidly changing conditions may be followed without difficulty. These meters are automatic in operation and can be used in conjunction with a recorder to provide permanent records. Also for the chemist is the conductivity controller: electrolytic conductance measurements afford a convenient and sensitive method for determining a number of factors of basic importance in industrial processes, and the usefulness of such measurements is greatly increased when they are applied to the automatic control of the process being monitored. The instrument shown consisted of a modified Wheatstone bridge network operated at a frequency of 2·9 kc./s., and incorporated an amplifier and relay circuit which enable electrical process control to be effected.

Examples of various miniature circuit units were to be seen at the exhibition. Silver conductors are screen-printed and fired, and resistors are formed with a series of baked-on graphite dispersions. The range of resistivities is from 10 ohms to 1 megohm per square, and one type of dispersion will withstand a temperature of 200° C. for one hour with no more than 1 per cent change in resistance. The resistor noise is of the same low order as that of grade-1 resistors (cracked hydrocarbon type). Ceramic capacitor tablets covering the range 1–10,000 $\mu\mu$F. per unit are available.

The exhibition showed that British instrument makers are keeping abreast of the times, and, in all fields of instrumentation where electronics can play a useful part, it is evident that the user may continue to expect to have new tools placed at his disposal.

J. A. SAXTON

MEDICAL RESEARCH COUNCIL

REPORT FOR THE YEAR 1950–51

THE report of the Medical Research Council for the Year 1950–51* follows the policy of the Council, initiated in the preceding report, of giving, not a complete picture of all that the Council is doing, but a selective account of its activities which discusses the most important work in progress, together with discussions of particular trends of the Council's activities. The report also contains a single classified list of papers published by the Council's individual research workers, an outline of the Council's research programme and the research programmes of each of its many Departments, and lists of the personnel of each of these Departments. An appendix to the report for this year gives in full the text of the memorandum on the future organization of medical research, submitted to Parliament in 1918 by the late Viscount Addison, a memorandum which placed the Medical Research Council under the authority, not of the Ministry of Health, but of a Committee of the Privy Council. Anyone who wishes to understand Viscount Addison's reasons for this wise move will find them here explained. Another section of the report pays tribute to the considerable labours of Viscount Addison on behalf of British medicine.

The particular trend of the Council's work that is discussed in the report is "The Training of Research Workers". The discussion of this important subject recognizes that the main responsibility for training these workers rests on the universities, with which the Council has always been closely associated. Agreeing with the late Sir Charles Sherrington that the best way to get scientific fruit is to cultivate the tree, the Council has from the first given grants to support research assistants in university and other departments and has helped to provide opportunities for the training of junior workers in the research of their own establishments. Recently the Council has increased facilities for research workers. It believes that by far the best training for them is actual investigation under the guidance of an expert, and a flexible scheme for the assistance of the training in research has been devised. This scheme is intended to meet individual needs, and there are three main aspects of it: research scholarships (formerly called studentships), clinical fellowships and travelling fellowships.

Postgraduate scholarships are intended for those who have graduated recently in medicine or science, although they include also arrangements for more senior workers, and supplement opportunities provided by the universities. They are available for workers training in any branch of medical science and are awarded for one year, being renewable for a maximum of three years. This scheme began in 1944, and 221 scholarships have so far been awarded. More than half of them have been for subjects allied to chemistry, and a quarter have gone to workers interested in the preclinical subjects.

The clinical fellowships are intended for more senior workers and were created because postgraduate studentships (scholarships) attracted few medical graduates to careers in clinical research. The stipend is that of a registrar in the National Health Service, and they carry continuation of the superannuation provided by departments of health. Provision is also made for any non-clinical work that may be necessary. Any academic or hospital department sponsoring an applicant is required to undertake to give the applicant an opportunity to return to that department if he desires to do so.

The Council has five groups of travelling fellowships at its disposal: Rockefeller fellowships in medicine, Eli Lilly research fellowships in medicine, Dorothy Temple Cross fellowships in tuberculosis, Alexander Pigott Wernher Memorial Trust fellowships in ophthalmology and otology, and French exchange scholarships in medical science. The first two groups are available to workers in clinical and non-clinical subjects, the third and fourth in the special subjects stated, and the fifth in non-clinical subjects only. All are normally tenable for one year. The report describes these fellowships and gives a table that summarizes the careers of those who have held them in the past.

---

* Committee of Privy Council for Medical Research. Report of the Medical Research Council for the Year 1950–51. (Cmd. 8584.) Pp. iv+214. (London: H.M.S.O., 1952.) 6s. net.

The selective account of the Council's work entitled "Some Aspects of Medical Research" is, like the similar section in the preceding report, a valuable discussion of modern knowledge of the following subjects: research on proteins, the preservation of spermatozoa and other cells at low temperatures, statistics in medical research, whooping cough, tuberculosis, antibiotics, diseases of the eye and skin, the experimental study of human skilled performance, climatological medicine, cortisone and adrenocorticotropic hormone, malaria, and insecticides. It is impossible, in the space available in this article, to do more than indicate in this way the scope of this interesting section. It does not cover, and it is not intended to cover, the full extent of the Council's activities and interests, the breadth of which is realized only by a study of the research programmes of the Council's numerous departments.

The reports of the Medical Research Council, and also those of kindred organizations, reveal the noble uses to which scientific work is actually being put. Not only is science daily saving the lives and mitigating the suffering of human beings and animals; it is also extending the span of life, fitting it to the demands of modern civilization and preparing for later generations a better and a healthier world. There is much in the history and literature of the world to remind one of man's desire to help his fellows and other living things; but readers of the reports of the Medical Research Council may well ask themselves where else, outside unpretentious documents such as these, a man may find a comparable record of human labour entirely devoted to the welfare of mankind. G. Lapage

PHOTOGRAPHY IN RESEARCH AT THE UNIVERSITY

On October 4 nearly two hundred people gathered at the Zoology School, Cambridge, to hear a series of short papers on the applications of photography to research in the university. This very successful all-day symposium was organized by the Scientific and Technical Group of the Royal Photographic Society and made possible largely through the enthusiastic co-operation of a number of Cambridge workers, including Prof. J. Gray, Dr. R. H. J. Brown, Mr. A. M. P. Brookes, Mr. Fairfax-Fozzard and Dr. J. S. Courtney-Pratt.

Mr. V. Gallafent opened the symposium by outlining the aims and objects of the Scientific and Technical Group in the advancement of photography. The Second World War, and its after-effects, have prevented the Group from acting on its agreed policy of fostering subsections in the provincial centres. The present meeting at Cambridge marked the first real step towards the realization of this policy; and it was clear that it was a popular one.

A résumé of photographic reciprocity failure by Dr. W. F. Berg led to an interesting discussion on the merits of latensification by a long, low-intensity exposure after the short camera exposure. Mr. G. S. Moore urged, from the floor, that full development in a low-contrast metol developer would give as much speed as could be achieved by latensification, but possibly the latter process gives finer grain at a given γ (which defines contrast in the image).

In a very clear paper, Mr. A. M. P. Brookes presented what might best be called a system of approach to any problem in high-speed photography as applied to engineering. It is usual to decide the exposure-time first. Still and ciné techniques differ inasmuch as the shutter-speed for a photograph destined to be examined as a still needs to be shorter than that for a ciné frame, where slight blurring helps to produce a jerk-free movement on projection. Mr. Brookes showed a graph from which the exposure-time could be read off against subject-speed after allowing for scaling-down in the camera. The graph was based on a 0·1-mm. movement of image on the emulsion. For illumination of the subject, counting the light output from a photoflood as 1, a studio light would be 10, a high-intensity mercury arc 50, a flashbulb 1,000, and a discharge tube 10,000.

Dr. R. H. J. Brown, of the Department of Zoology, Cambridge, was principally interested in the study of animal movements—the flexure of a pigeon's wings, fish swimming, etc. He dealt, in his paper, mainly with the problems of illumination. For micro-cinematography the BTH type *FA5* lamp having a source 4·5 mm. in length is very good. It can be run continuously at 125 W. or flashed at a rate equivalent to 3½ kW.

Mr. H. S. L. Harris described experimental difficulties in connexion with the bringing into operation of a mercury-vapour flash-tube for the photoelastic study of the stressing of gear teeth while running under load.

In the afternoon session Mr. R. G. Horner read a short paper on the limitations of colour photography in the recording of colour. Colour photography is sold to the public in order to give pleasing pictures, and it was never intended as a simple short-cut to colorimetry. When used for recording colours, it is necessary to apply all the standard photometric techniques used in photographic photometry.

A particularly interesting paper was presented by Prof. J. S. Mitchell (professor of radiotherapeutics in the University of Cambridge) dealing with ultra-violet and fluorescence photography, particularly that of cancerous tumours. Work is in progress on the relation between the disturbance of cellular nucleic acid metabolism (as revealed by ultra-violet absorption) and the production of structural changes in chromosomes by the therapeutic doses of irradiation.

Animal experiments have confirmed the increased fluorescence to ultra-violet light of the actively growing parts of the tumour and some other tissues following the injection of tracers. Prof. Mitchell appealed for guidance in colour-photographing the yellow fluorescence of the dissected tissues so as to yield quantitative results. A similar appeal was made by Dr. K. W. Rizk, who is engaged in recording the flow patterns that occur when water containing a blue indicator (such as litmus) is injected into a tank containing a colourless solution that turns the indicator red. Dr. Rizk was disappointed to find that the boundary between the blue central cone of the jet and the red mantle varied according to the camera exposure. No help was forthcoming from the meeting for Prof. Mitchell or Dr. Rizk beyond a re-emphasis of the limitations of commercial colour-processes.

In the section on radiation microscopy, Dr. V. E. Cosslett (Cavendish Laboratory) considered the suitability of photographic materials for electron and X-ray work. For ordinary work the available materials are satisfactory, but for some purposes it would be advantageous to have specially improved materials. Dr. Cosslett appealed for more work to be carried out on the relationship between electron voltage and the characteristics of the photographic materials exposed to them. Very puzzling is the marked difference in response of photographic emulsions to electrons and X-rays.

Dr. J. W. Menter (Physics and Chemistry of Surfaces Laboratory, Cambridge) showed some very fine electron-reflexion micrographs of solid surfaces. These were obtained using a Metrovick *E.M.*3 electron microscope that had been adapted for reflexion work.

Mr. W. D. Kemp dealt with the application of television to the recording of motion-picture films. There is no space here to follow the detailed technical argument, but it was summed up well in the short film that was projected. The quality was far above anything seen on the broadcast television screen. Questioned as to whether the lines had been eliminated by spot-wobble, Mr. Kemp replied that they had been visible on the negative but were lost in the printing stage.

In the last paper of the symposium Mr. J. G. Yates described the experimental difficulties attending the slow-speed recording of low-frequency 'noises' such as the spontaneous variations in carbon resistors that occur under load.

FULMER RESEARCH INSTITUTE

OPEN DAY

AN open day was held at the Fulmer Research Institute on September 30 to mark the completion of the first five years of work at the Institute; it was also the occasion for unveiling a memorial plaque to the founder, the late Colonel W. C. Devereux. After welcoming the guests, Mr. Percy Horsfall, chairman of the group of companies forming Almin, Ltd., explained that the Institute has been provided with the necessary capital by his organization, but that the Institute facilities are available to all without any preference to the Almin group. In the absence of Lord Hives, who had gone abroad, the unveiling ceremony was performed by Sir Archibald Rowlands, permanent secretary of the Ministry of Supply, who was a close personal friend of Colonel Devereux. In a memorable and moving speech Sir Archibald described Colonel Devereux as a happy man with great abilities, enormous drive and a warm heart, who had provided in the Fulmer Research Institute something for Great Britain similar to the well-known Battelle and Mellon Institutes of the United States.

After luncheon Lord Waverley (better known to many as Sir John Anderson) spoke on the successful efforts that have been made in Great Britain since the First World War to make good the deficiencies in the national scientific equipment, particularly in the application of science to industry. He recalled that some seven years ago at a conference of the Federation of British Industries on the application of science to industry, he had expressed regret at the absence in Britain of any institution comparable with the Battelle and Mellon Institutes. Despite the amazing increase in scientific effort through the larger industrial units, the universities and the research associations, and other establishments under the ægis of the Department of Scientific and Industrial Research, Lord Waverley still thought there is scope for further effort and expressed the hope that the work of the Fulmer Research Institute would be multiplied many times in other fields.

After paying a personal tribute to Colonel Devereux, Mr. E. A. G. Liddiard, director of research in the Institute, outlined the progress made by the Institute over the first five years, during which the income, now approximately £78,000 a year, has more than trebled and the staff more than doubled. All the income came directly from research contracts, and the Institute received no other income in the form of endowments or government grants. About half the total income was derived from government contracts, and there was a substantial proportion of direct dollar-earning sponsorship from the United States and Canada. There was, however, a steady increase in the volume of work for British industry and he looked for further growth in the future. He considered that the problem most appropriate to a sponsored research institute is one in which research results need considerable expenditure in subsequent development work, and it is essential that those incurring these costs should be assured of a return for their expenditure and for the risk taken by having some form of monopoly in these new developments—preferably in the form of patents covering the original research results. The connexions established in the United States and Canada would, he said, help in the full exploitation of research results obtained for British sponsors.

Sir Frederick Handley Page, on behalf of the guests, thanked the hosts and stressed the opportunities available in the Institute for British industry, particularly for small firms which cannot afford the equipment or staff necessary for the solution of a particular problem.

The laboratories of the Institute were open for inspection and contained exhibits of various items of work completed and in progress. In the Physical Chemistry Section the work of Dr. P. Gross and his colleagues on the refining of metals by reactions involving metal halide vapours was illustrated. This included the determination of heats of formation of metallic halides and the equilibrium and kinetics of various reactions, particularly the reaction $2Al + AlCl_3 \rightleftharpoons 3AlCl$, which forms the basis of the so-called 'catalytic' distillation of aluminium. A small pilot-plant operating this refining process was an important feature. Samples of titanium metal produced in the laboratory by different reactions, details of which were not available, were on show together with samples of titanium trifluoride and of beryllium produced by indirect distillation.

In the Physics, Metallurgy and Engineering Sections, under Dr. A. H. Sully, alloy research included an investigation into the mechanism of age-hardening and work on aluminium–bronze and aluminium–tin bearing metals. The aluminium–copper–cadmium alloys developed by the Institute were claimed to have properties similar to the duralumin-type alloys but to be free from any tendency to age at room temperature and to have exceptionally good hot-working properties. Work on high-temperature materials included an investigation into the ductile-brittle transition of chromium and of metal-ceramic aggregates, and a good deal of interest was shown in the development of low-emissivity protective ceramic coatings for combustion chambers of gas-turbine engines. The Physics Section employs Guinier-type single and double monochromators for studying structural changes in age-hardening alloys; and in the Engineering Section high-temperature fatigue and creep testing in both tension and compression was in progress, and the use of strain gauges for evaluation of residual stresses and for recording movements in large structures was illustrated. In the Corrosion Section work was in progress on vapour-phase impregnation of iron and steel with silicon, hydrogen embrittlement of steel, and electrodeposition of manganese. Attention was directed to the marked influence of directionality in light-alloy extrusions on resistance to corrosion and stress corrosion.

A large proportion of the equipment and apparatus on view had been constructed in the laboratory workshops, including the pilot plant for aluminium distillation, the vacuum induction and arc-melting furnaces, gas X-ray sets, compression creep machines, furnaces and temperature controllers.

INDIAN ASSOCIATION FOR THE CULTIVATION OF SCIENCE

THE annual report of the Indian Association for the Cultivation of Science for 1951–52* records the completion of the transfer to the Association's new buildings at Jadarpur and the removal of the Department of Organic Chemistry in June 1951, but research work was considerably curtailed by the removal. Research schemes for the X-ray study of coal and for the construction of osmometers for high-polymer research, sanctioned by the Council of Scientific and Industrial Research, were continued, and a new scheme was sanctioned for the construction of a light-scattering apparatus for measuring the molecular weight, size and shape of high polymers.

In the Department of X-rays and Magnetism a systematic investigation has been undertaken into the structures of phenanthrene derivatives, particularly hormones, and N. N. Gupta has been able to show that the nature of the low-angle scattering of X-rays does not depend upon the internal structure of the crystal but only on the size and shape of the particle. R. K. Sen has perfected the method of determining the elastic constants of a crystal by the X-ray diffraction method, and the limitations of the Jahn–Jeller effect have been investigated. Measurement of the conductivity of single crystals of graphite from 80° to 500° K. has been completed, as well as the major equipment for the liquid hydrogen plant.

In the Department of Optics, studies on *p*-dichlorobenzene have shown that crystals cooled once below 0° C. give a different Raman spectrum from crystals not treated thus. New lines in the low-frequency region have been observed in the Raman spectra of *p*-xylene and benzyl bromide, and the ultra-violet absorption spectra of acetophenone, methyl benzoate ethylbenzene and *iso*propylbenzene have been studied in the liquid and solid states, as well as those of the cresols, *o*- and *p*-xylene, benzyl alcohol and benzyl chloride. In the Department of Theoretical Physics, besides work on the meson fields and nuclear scattering, good progress has been made in improving the Born approximation by taking higher terms of a onsistent expansion in powers of the constant denoting the strength of the coupling between the field and the particle.

In the Department of Physical Chemistry detailed study has been undertaken of chain transfer in uncatalysed polymerization of styrene methyl methacrylate and methyl acrylate in solvents, and investigations have also been made of the polymerization of methyl methacrylate with hydrogen peroxide in non-aqueous solvents, triphenylmethylcellulose and the solubilization of mixed detergents. In the Department of Inorganic Chemistry, which formally started in July 1951, preliminary investigations were made on co-ordination complexes and ion-exchange methods in inorganic chemistry. Lists of papers published during the year are included, with lists of books and periodicals added to the Library.

THE CHAYEN PROCESS FOR EXTRACTION OF OILS AND FATS

THE normal process for the extraction of oils and fats from naturally occurring cellular material involves the use of a hot solvent. This process requires steam heating for many hours, resulting in the formation of some undesirable degraded products.

British Glues and Chemicals, Ltd., gave a demonstration of a new process devised by Mr. I. H. Chayen and his associates at their Stratford factory in London on October 28, when they were able to show an entirely new technique. In this process, crushed bones are passed, together with a stream of water, into a modified disintegrator where complete fat rendering is achieved in about one second while the material is in the mill. In this disintegrator, the normal blades had been replaced by beaters arranged to give a clearance of about 4 in. from the mill-casing. With a blade tip-speed of about 12,000 ft. per min., the high-speed impulses given to the water break open the cell-walls of the tissue and enable an easy extraction to follow.

The fat and degreased bone leaving the mill are separated by gravity from the water stream, the fat being skimmed off and purified and the bones passed on for drying, when they are ready for glue making or for incorporation in bone meal.

The importance of this technique lies not only in the fact that it has provided a much improved process for one industry, but also that it has provided a new chemical engineering tool and principle, namely, the use of high-speed impulses to break down mechanical barriers, in this case the cell-walls. The application of high-speed vibrations in the chemical process industries is as yet a largely unexplored field, but this application is already showing a great reward. The degreased bone is ready for glue making in 8 min. and the fats are of much finer quality, since the process is carried out in the cold. The continuous process offers many advantages compared with the old batch one in the form of simplified plant layout and operation, as well as very considerable saving in fuel.

This is an interesting example of a machine produced for one purpose being applied with but small alteration to provide a new mechanism in another industry. British Glues, Ltd., are to be congratulated not only on their discovery of a new principle, but also on the quick way in which they have passed from the pilot plant to the commercial plant, for they now have this process in use in four factories, including one in Canada. They were able to show on a pilot plant the same technique for handling herrings, and the next development may well be in the valuable fish-liver industry.

Extractability of the Lotmar–Picken Material from Dried Muscle

Bear and Cannan have reported[1] new experiments with muscle exhibiting the so-called Lotmar–Picken[2] X-ray pattern. We, too, recently found a muscle (in our case a *Mytilus* adductor) which gave the pattern, and we have repeated their observation that after extraction with water it gave only the normal α-pattern characteristic of myosin. In addition, our specimen gave a number of new reflexions in the form of almost continuous circles, distinguished from the Lotmar–Picken reflexions in showing scarcely any orientation and in having a more grainy texture; these reflexions, too, disappeared on extraction with water. We attribute them to a new substance which we provisionally call '*X*'. An analysis of the diffraction pattern on these lines is given in the first three columns of the accompanying table.

Whole muscle			Extract
Lotmar–Picken material		Substance '*X*' (continuous circles)	
Equator	First layer line		
0·075 m			
		0·080 m	0·076 m (*X*)
0·086 vw			
	0·105 vw		
0·107 m			0·106 m (LP)
		0·118 s	0·118 m (*X*)
	0·127 m		0·127 m (LP)
0·128 vw			
0·135 w			0·133 w (LP)
	0·140 w		0·139 w (LP)
0·145 m			0·144 w (LP)
		0·161 mw	0·160 m (*X*)
		0·170 mw	0·167 m (*X*)
0·176 w			0·172 w (LP)
	0·178 w		0·178 vs (NaCl)
		0·186 w	0·186 w (*X*)
		0·193 vw	0·189 w (*X*)
		0·221 m	0·219 w (*X*)
		0·229 w	0·226 w (*X*)
			0·251 s (NaCl)

Figures are sin θ/λ values. Letters indicate intensities as follows: vs = very strong; s = strong; m = moderate; mw = moderately weak; w = weak; vw = very weak. In col. 4, lines attributed to the Lotmar–Picken material are marked 'LP', those attributed to substance '*X*' are marked '*X*', and those attributed to sodium chloride are marked 'NaCl'.

We have obtained some new information by evaporating to dryness the water used to perform the extraction. The residue was seen under the microscope to contain: (*a*) single highly birefringent crystals, and (*b*) soft hygroscopic dendritic deposits which had the appearance of being crystalline but were not detectably birefringent. After thorough drying, the residue gave an X-ray powder pattern which can be analysed into three components: (*a*) strong lines with spacings characteristic of sodium chloride, (*b*) a set of lines the spacings of which are identical with the stronger lines of the Lotmar–Picken pattern, and (*c*) a set of lines corresponding to the continuous circles in the pattern of the original muscle, and presumably due to substance '*X*' (see column 4 of table). This analysis is confirmed by the fact that components (*a*) and (*c*) have a more pronounced graininess than (*b*), and by the observation that on exposure of the specimen to damp air part of the pattern disappears, namely, the lines due to the Lotmar–Picken material, which is presumably deliquescent. We provisionally identify the hygroscopic dendritic deposits with the Lotmar–Picken material and the birefringent crystals with substance '*X*'.

We made two other observations of interest: (*a*) after heating the dried extract to 100° C. for 1½ hr., its X-ray pattern (including the Lotmar–Picken component) was unchanged; and (*b*) a dried water-extract of a 'normal' muscle (exhibiting neither the Lotmar–Picken pattern nor that due to substance '*X*') gave a powder pattern made up of the lines of sodium chloride and the lines characteristic of substance '*X*'; no Lotmar–Picken lines were present.

These observations appear to establish the fact that the Lotmar–Picken material is a soluble, crystalline substance which can be extracted from the muscle by water; and thus, since actomyosin and myosin are most unlikely to be extracted under these conditions, they render it very improbable that the Lotmar–Picken pattern is merely a manifestation of an unusually perfect orientation of myosin. The results argue almost equally strongly against the material being a protein of any sort; the powder pattern of the extract contains no lines with spacings greater than 6·6 A., and the smallest spacings in it which are attributed to the Lotmar–Picken material are of 2·9 A. The powder patterns of all dry protein crystals hitherto examined have included lines of much greater spacing than the former, and have generally faded out before reaching the latter, value. Thus we agree with the view expressed by Bear and Cannan that the Lotmar–Picken substance is probably not a protein, and consider that our results lend additional support to it. The close agreement between one cell dimension of the Lotmar–Picken substance and the axial repeat of myosin would therefore appear to have no significance, except perhaps in the sense that it may encourage the substance to crystallize in the muscle in preferred orientation.

In order to exclude absolutely the possibility that the Lotmar–Picken substance is a protein, we attempted (*a*) to recrystallize the material from a solution which had been heated to 100° C., (*b*) to pass a solution of it through a fine-pored dialysis membrane and then to recrystallize it. These experiments were unsuccessful; but the amount of material available was insufficient to repeat them, and we do not regard the negative results as significant—crystallization of the substance is always a matter of chance, for we found that it did not take place on every occasion when we dried the initial water extract from the muscle. For the same reason we do not consider that our failure to obtain a Lotmar–Picken pattern from the dried extract of a 'normal' muscle proves that the substance is absent from such muscles.

Is α-Keratin a Coiled Coil ?

All recent work[1–4] has confirmed that the structure of the synthetic polypeptide poly-γ-methyl-L-glutamate is based on the α-helix of Pauling and Corey[7]. This structure gives a strong 1·5-A. reflexion on the meridian, and both MacArthur[8] and Perutz[1] have shown that this reflexion also occurs in α-keratin. This suggests forcibly that the α-helix forms an important part of α-keratin.

There are certain difficulties in this idea. One of the main features of α-keratin is the strong reflexion at 5·15 A. on, or very close to, the meridian. The normal α-helix gives strong reflexions on the 5·4-A. layer line, but displaced from the meridian. The difference in spacing is not an insuperable objection, since the α-helix might be more tightly coiled; but it is difficult to see how one could obtain such a narrow meridional arc as is observed for α-keratin, even allowing for our ignorance of the details of the side-chain arrangement.

One way to bring the reflexion nearer to the meridian would be to tilt the α-helix. Since the α-keratin pattern is of wide occurrence, one would expect the tilt to be a constant feature of the structure. The most likely general solution is that the α-helix is bent into a super-helix, or coiled-coil. If the α-helix is twisted into a super-helix with a pitch angle of about 18°, its projection on to the axis would have a periodic variation in density at intervals of $5{\cdot}4 \cos 18° \simeq 5{\cdot}1$ A., and so might explain the observed meridional reflexion which corresponds to this spacing. A pitch angle of 18° could be obtained, for example, from a super-helix of radius 10½ A. (the probable distance between helices) and axial spacing 198 A. (the repeat of African porcupine quill)[8,9].

It is possible to make a rough estimate of the energy required to deform the α-helix by this amount by assuming that (1) the forces preventing small rotations about single bonds are small; (2) the hydrogen bond can be fairly easily deformed by small amounts in direction; (3) the main restoring force comes from the resistance of the hydrogen bonds to deformation in length.

Assuming a force constant for a hydrogen bond of, say, 3×10^4 dynes/cm. (see, for example, Davies[10]), the average energy per residue to deform the α-helix by the amount described above is about one-tenth of a kilo-calorie per residue, which is small. This energy increases roughly as the fourth power of the pitch angle, so that the α-helix can easily be bent through small angles, but resists large deformations.

So far, no reason has been given why the α-helix should be deformed. It seems probable that this is due to the difficulty of fitting together the side-chains of two adjacent α-helices.

I should like to suggest that there may be a general plan underlying the detailed packing of all the various side-chains found in proteins. If the side-chains of the α-helix are thought of schematically as knobs on the surface of a cylinder, then it is found that the pattern on this surface consists of knobs alternating with 'holes', that is, spaces into which the knobs from a neighbouring α-helix could fit. The position of these holes is roughly independent of the exact nature of the surrounding side-chains.

In poly-γ-methyl-L-glutamate, the side-chains are long and flexible and they can reach out towards the nearest hole without deforming the α-helix. In proteins, on the other hand, the side-chains are, on the average, smaller and less flexible, and neighbouring helices are nearer together (10½ A. compared with 12 A. for poly-γ-methyl-L-glutamate). It is therefore not unreasonable to simplify the undoubtedly complicated packing of side-chains into a set of standard rigid knobs fitting into standard holes.

It is impossible to pack such models of the α-helix closely side by side, since a good fit in one place produces a bad fit somewhere else, due to the non-integral nature of the helix. However, it can be shown that by deforming the helices into coiled-coils the knobs can be made to interlock systematically. The energy for deforming the helices could come from the closer fitting together of the side-chains.

The objects of this communication are to stress that the α-helix can be deformed an appreciable amount if the deformation is systematic, to suggest that there may be a general plan underlying the packing together of side-chains, and to show that these two ideas lead to a coiled-coil which may explain some of the data[11] better than a straight α-helix.

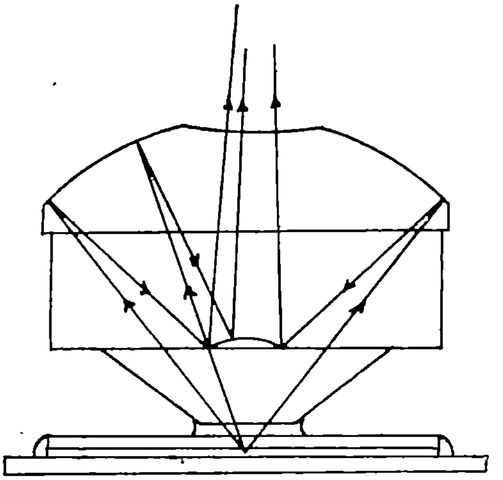
An Easily Used Ultra-Violet Microscope Objective

The ultra-violet microscope is a useful cytochemical tool because it enables one to locate and measure the amounts of absorbing substances in cells (see, for example, Caspersson[1]). It is a considerable advantage if the microscope objective is achromatic throughout the visible and ultra-violet regions of the spectrum; focusing of the microscope in visible light is then simplified, and many wave-lengths may be used simultaneously in order to obtain an absorption curve. Reflecting microscopes are completely achromatic, and hence have been much favoured for cytochemical use (cf. refs. 2 and 3, for example). After several years of use of reflecting objectives, we find they have three main disadvantages: (*a*) the numerical aperture at present possible, ≃ 0·65, is rather low for many purposes; (*b*) the ultra-violet reflectivity of front-surface mirrors sometimes deteriorates rapidly; (*c*) very exact positioning of the mirrors relative to each other is necessary. If the mirrors are preset during manufacture, dislocation may take place in use, thus necessitating return to the maker; if, however, the objective is adjustable, some users may have trouble in making the adjustments. In this communication we describe a simple objective which has been designed to overcome all these disadvantages.

The numerical aperture of a reflecting objective may be increased by a factor μ when a normal-incidence immersion lens of refractive index μ is placed over the object (cf. ref. 4, for example). The lens and two mirrors of the objective must all be adjusted relative to each other, and, as this is much more difficult than adjusting a simple reflecting objective, such compound objectives are not likely to come into general use. If the normal-incidence immersion lens is enlarged so that it fills the space between the mirrors, the objective is transformed into a solid type[5] (see diagram). The difficulty of finding a suitable means of manufacturing such an objective for ultra-violet use has now been overcome. Solid objectives composed of three pieces of glass cemented together with canada balsam have been made[6] for use with visible light. For use with ultra-violet, our objective is made of fused quartz, and, because no really satisfactory ultra-violet transmitting lens cement is known, the parts are optically contacted. Before being permanently contacted, the mirrors are centred by sliding one component of the objective over the other, while viewing a pin-hole test-object.



The mirror-pair consists of two spherical surfaces which would give 0·60 numerical aperture in air. In the solid objective, the refractive index is that of fused quartz and therefore the numerical aperture is $\simeq$ 0·90. The central obstruction of numerical aperture is 35 per cent and the focal length is 1·7 mm.

The objective is made to screw on to any ordinary microscope and to be parfocal with normal objectives. To obtain exact achromatism, it is necessary to use an immersion liquid having the same dispersion as fused quartz. Water almost fulfils this requirement, and the small residual chromatic aberration is compensated by slight refraction at the quartz–air interface where the light leaves the objective. Spherical aberration, due to refraction in the water layer between coverslip and objective, is compensated by suitable separation of the two mirrors. The residual spherical aberration is approximately λ/8 for 2500 A. The only aberration which limits field-size is coma, and this reaches the Rayleigh limit[7] at a field diameter of $\simeq$ 50 microns for 5400 A. The objective may be designed for use with any thickness of coverslip up to several millimetres, and hence is very suitable for looking through thick windows on pressure-vessels, etc. Coverslips of 0·5 mm. and thicker have the advantage of not cracking when roughly treated.

Objectives of this type have proved very satisfactory during test. There are no adjustments to make, and the objective is no more difficult to use than any normal refracting immersion objective. Achromatism is exact and, when focused for visible light, the objective is also in focus for ultra-violet. Thus really easy ultra-violet microscopy is made possible for any biologist. The mirror surfaces are in contact with the quartz and protected from deterioration due to the atmosphere.

We would like to thank Prof. J. T. Randall for much encouragement during this work.

Magnetostrictive Effect and the Δ-*E* Effect in Nickel

In connexion with the communication in *Nature* of December 1, 1951, p. 963, on sound propagation in ferromagnetic materials, the following experiments may be of interest.

Several authors have remarked upon the change of Young's modulus by the Δ-*E* effect in ferromagnetic materials. Giebe and Blechsmidt[1], for example, excited nickel rods in their resonant modes by their magnetostrictive effect, and detected maxima of vibrations by the same principle. They observed alterations of resonance frequencies when the rods were placed in a magnetic field, and ascribed them to changes in the elasticity due to the Δ-*E* effect. They, and others, do not seem to have noticed that the magnetostrictive effect may modify the changes in resonant frequencies caused by the Δ-*E* effect.

Due to the magnetostrictive effect, there is an interchange of vibrational mechanical energy and magnetic energy, and it can be shown that the ratio between these two forms of energy in a longitudinally vibrating magnetostrictive rod in a magnetic field is expressed by :

$$\frac{W_{\mathrm{m\cdot g.}}}{W_{\mathrm{m.ch.}}} = k^2 = \frac{8\,\mu\varkappa\lambda}{\pi^2(2n+1)^2 E},$$

where μ is permeability of material, λ is magnetostrictive constant, ϰ is inverse magnetostrictive constant, E is Young's modulus, $(2n + 1)$ is number of vibrational mode, n being an integer, while k is usually called the coupling constant. For even modes, the coupling constant is zero, and it is consequently impossible to excite a rod by the magnetostrictive effect in these modes. If the rod is surrounded by a coil, the frequencies of the modes where the coupling factor has a finite value will, however, depend on the impedance between the terminals of the coil in addition to the elasticity and density of the material.

If the coil is short-circuited, no induction can be set up by the inverse magnetostrictive effect, and consequently no magnetostrictive force is developed. The resonance frequencies of the rod will in this case depend on the density and the elasticity only,

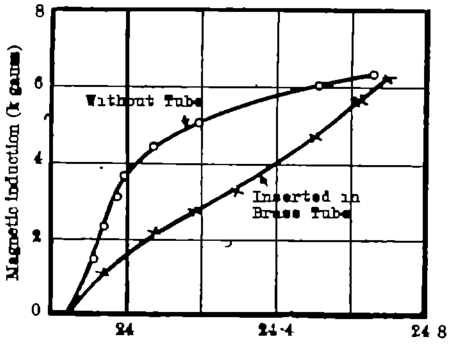

Fig. 1. Deviations of fundamental frequency in nickel rod, with and without surrounding brass tube

the latter modified by the Δ-*E* effect. If, on the other hand, the rod is vibrating in an odd mode, and the surrounding coil is on open circuit, the magnetostrictive force developed will modify the vibrational behaviour of the rod. This last change in resonant frequencies is due to the magnetostrictive effect only, and it is thus possible to separate the two effects. The following measurements show the magnitudes involved.

A laminated nickel rod, 10 cm. long with a cross-section of 1 cm.^{2}, is longitudinally excited at one end, and the vibrations are detected at the other. In order not to have any reaction from the mechanical generator and detector impedances, a thin wire, approximately 1 cm. long, is soldered on to the nickel rod at either end, and the excitation and detection by two Rochelle salt transducers take place through these wires. Thus no electro-mechanical effect in the rod itself is used for excitation or detection. Permanent magnets are used to produce a polarizing field of varying magnitude in the rod. The rod is then excited in its fundamental mode, in which the coupling according to the formula should be a maximum (10–20 per cent in practical cases). First, the rod is vibrating freely, and the change of resonance frequency versus magnetic field is plotted. Next, the rod is inserted in a short-circuited coil in the form of a brass tube. The change in frequency is again plotted against magnetic field. The results of these two measurements are shown in Fig. 1.

As will be seen, the change of resonant frequency caused by the Δ-*E* effect is counteracted by the magnetostrictive effect and in a certain range of magnetic field is of the same order. If the rod is excited in its first harmonic frequency, no coupling occurs, and no difference is measured when the rod is inserted in the brass tube. The change in resonance frequency is now entirely due to the Δ-*E* effect, and Fig. 2 shows the frequency deviations.

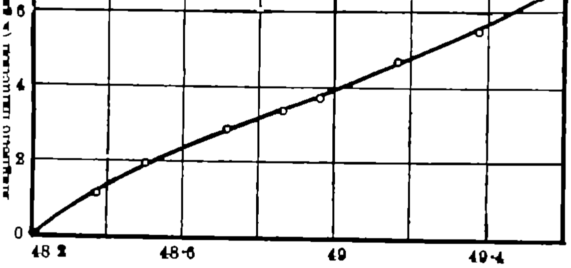

Fig. 2. Deviations of first harmonic frequency in nickel rod

Since the measurements of Giebe and Blechsmidt were carried out at high modes of vibrations, the coupling constant is negligible, and no measurable change would be detected when the impedance between the terminals of the coil is altered. Their results are therefore still valid. For the lower modes, however, the magnetostrictive effect must be taken into account when vibrations are studied.

No measurements were made of the vibrational losses in the rod. It is likely that these will also depend on any induction set up by the magnetostrictive effect, with resulting eddy currents. The present results are part of an investigation into vibrating magnetostrictive systems, and the phenomenon of coupling effects will be presented there in greater detail.

Ultra-Violet Band System of Strontium Oxide (SrO)

THE investigations hitherto made have shown that three band systems belong with certainty to the strontium oxide molecule (SrO); the first of these is situated in the infra-red, the second in the blue and the third in the ultra-violet region. Mahanti made vibrational analyses of the blue and ultra-violet systems[1]. A vibrational and rotational analysis of the infra-red system, a $^1\Sigma - {}^1\Sigma$ transition, was communicated by us in 1949[2]. This analysis shows that the vibrational frequencies of the lower $^1\Sigma$ state coincide extremely well with those of the lower state of the blue system. Thus for $^1\Sigma$ we found $\omega_e'' = 653{\cdot}4_7$ and $x_e''\omega_e'' = 4{\cdot}0_8$, as compared with $653{\cdot}4_7$ and $4{\cdot}0_8$ for the lower state of the blue system. In our paper we mentioned this agreement and assumed that the infra-red and blue systems have the same lower state. Recently, Budó and Kovács have privately communicated to us that they have made a successful rotational analysis of the blue bands. The transition is $^1\Pi - {}^1\Sigma$, where the lower state is the same as for the infra-red bands.

The ultra-violet band system of strontium oxide, situated between λ 3200 and λ 3700 A., has been investigated with the 21-ft. grating of this institute. The rotational analysis of the 2,0, 1,0 and 0,0 bands shows that the system is a $^1\Sigma - {}^1\Sigma$ transition, where the lower state is the same as that of the blue and infra-red systems. The constants derived for the upper state are

$$B_0' \sim 0{\cdot}272 \text{ cm.}^{-1} \qquad B_2' \sim 0{\cdot}269$$
$$B_1' \sim 0{\cdot}271 \text{ cm.}^{-1} \qquad D' \sim 0{\cdot}3 \times 10^{-6}$$

No upper vibrational constants have yet been calculated. The bands contain several perturbations in the upper state.

From measurements of the band-heads (*R*-heads) of the ultra-violet system, Mahanti has calculated for the lower state of this system $\omega'' = 679{\cdot}13$ and $x''\omega'' = 9{\cdot}13$. At first glance these values do not suggest that the lower state is the same as that for the other systems. The deviations from these values and those obtained from origins are not greater, however, than may be expected.

A more detailed paper on the ultra-violet bands will appear in *Arkiv för Fysik*.

Spectrum of the Compton Radiation from Solids

THE spectrum of the Compton radiation from *free* atoms has been calculated[1] and was found to consist of a band with a sharp limit towards short wave-lengths. At the same time some 'electronic Raman lines' are supposed to exist between the limit and the line of the primary radiation. In the case of *solids*, this picture should be modified because the discrete energy-levels are replaced by energy-bands. The form of the spectrum will depend on the density distribution of states in the highest occupied energy-zone and in the free zone above it. The sharp limit and the electronic Raman lines will be replaced by broad bands, possibly with a structure. If the highest occupied zone is filled and there is a forbidden zone above it—as in the case of insulators—the broad Compton band should show a limit towards short wave-lengths. The energy shift between this limit and the primary line will be equal to the breadth of the forbidden zone. Although most experiments on Compton scattering have been carried out on solids, such a structure has not yet been observed because of the short wave-lengths used. In the following an account is given of experiments showing the above effect.

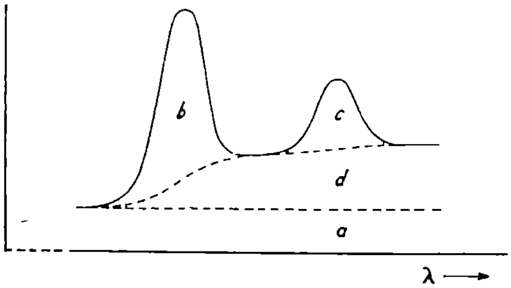
Unfiltered copper radiation is scattered on beryllium and carbon at angles between 17° and 45°. The scattered radiation is collected in a bent crystal spectrometer and is then investigated spectroscopically with a Geiger–Müller counter moved along the Rowland circle. The form of a typical spectrum obtained is shown in the accompanying graph. The surface under the curve can be divided into the following areas: (*a*) background, (*b*) line α_1, (*c*) line α_2, and (*d*) the Compton band.

(*a*) *Beryllium.* Experiments were carried out at angles of 20·5°, 25·5°, 30°, 35° and 40°. In all cases the Compton band starts near the primary line, showing that no limit towards short wave-lengths exists. Also in no position of the spectrum does it show an appreciable maximum.

(*b*) *Graphite.* The Compton band at 17° was found to have the same properties as that of beryllium.

(*c*) *Diamond.* At angles of 17° and 30° the Compton band has no appreciable intensity near the primary line. It could only be measured at longer wave-lengths than the α_2-line. At an angle of 35° its intensity is sufficient to show that it starts between the lines α_1 and α_2 at a position corresponding to a shift of 7·5 eV. from the primary line. A similar hump can be observed at a position of the spectrum that corresponds to a shift of 7·5 eV. from the α_2-line.

The spectra obtained agree fully with the current theory of solids. The electrical conductivity of beryllium leaves no possibility for the existence of a forbidden zone. Also, the fact that the absorption edge coincides with the high-energy limit of the emission line proves that this view is correct.



A graphite single crystal irradiated in such a way that the incident and the scattered radiation are contained in the basal plane should at $T = 0$ give a Compton band with a zero intensity at zero shift and with increasing intensity as the shift increases[2]. The present experiment does not show this behaviour because $T \neq 0$ and because the graphite was polycrystalline.

Diamond has a fully occupied zone that is separated from the next free zone[3] by a forbidden zone of about 7 eV. This has been found from absorption experiments in the ultra-violet. The present experiments also indicate the existence of such a forbidden zone.

A detailed report on the above experiments will appear in the *Arkiv for Fysik*.

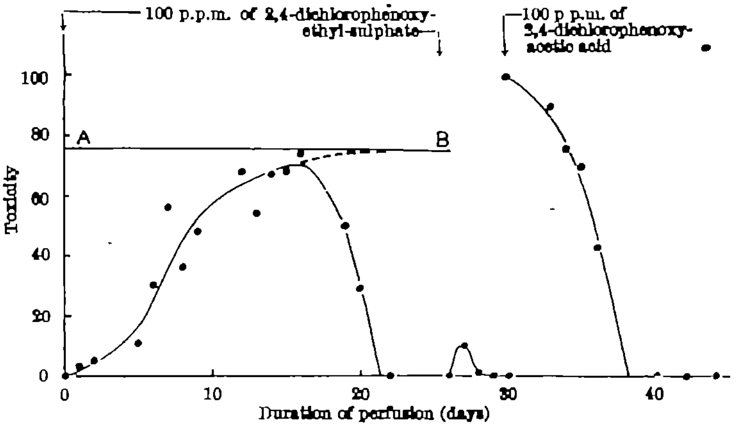
Fate of Sodium 2,4-Dichlorophenoxyethyl-sulphate in the Soil

SODIUM 2,4-dichlorophenoxy-ethyl-sulphate, a chemical of low intrinsic phytotoxicity, can be sprayed in relatively concentrated aqueous solutions on to plants normally sensitive to the hormone herbicides, without serious damage to them; but when it comes into contact with the soil, a high phytotoxicity is generated, sufficient to give satisfactory control of weed-seed germination in the surface layers of the soil[1]. The toxic compound arising from it has been assumed to be 2,4-dichlorophenoxyacetic acid (2,4-D).

To check this assumption, the behaviour of sodium 2,4-dichlorophenoxy-ethyl-sulphate in soil has been followed using the perfusion technique described for previous investigations on the herbicides 2,4-D and MCPA (2-methyl-4-chloro-phenoxyacetic acid)[2]. Solutions of 100 p.p.m. of the substance have been perfused continuously through garden loam and the changes in phytotoxicity of the perfusate followed by the cress root-growth assay technique[3]. The results of a typical experiment are shown in the graph, where toxicity is expressed in 2,4-dichlorophenoxyacetic acid equivalents (p.p.m.). Toxicity is generated slowly at first; but the rate increases up to about the eighth day, suggesting the proliferation of an organism adapted to bring about the interconversion. Later, the toxicity curve flattens out, probably due



Time course of toxicity in soil solutions on perfusing with 100 p.p.m. sodium 2,4-dichlorophenoxy-ethyl-sulphate (two successive perfusions) and then with 100 p.p.m. 2,4-dichlorophenoxyacetic acid

to the exhaustion of the dichlorophenoxy-ethyl-sulphate substrate, and becomes asymptotic to the line *AB*, corresponding to a concentration of 75·5 p.p.m. 2,4-dichlorophenoxyacetic acid, which is the theoretical concentration that would be generated in the perfusate by the complete conversion of the dichlorophenoxy-ethyl-sulphate.

After sixteen days, a rapid fall sets in and all toxicity is lost after twenty days. When 2,4-dichlorophenoxyacetic acid itself is perfused through fresh soil, no change in toxicity is noted for about fifteen days, after which a similar rapid detoxication occurs[1]. These almost identical time-relationships for the two detoxications is a strong indication that the dichlorophenoxy-ethyl-sulphate generates 2,4-dichlorophenoxy-acetic acid. During initial perfusion with dichlorophenoxy-ethyl-sulphate the accumulated 2,4-dichlorophenoxyacetic acid would induce the growth of a population of organisms adapted for its breakdown, giving, therefore, a lag phase characteristic of that organism[2].

The subsequent perfusion of fresh sodium 2,4-dichlorophenoxy-ethyl-sulphate solution (at twenty-six days in this experiment) fails to generate a similar high toxicity. In the first day only a small activity develops, but this disappears in the next twenty-four hours. Obviously the detoxicating organism is capable of destroying all the toxic compound as fast as it is produced. This indicates that the use of dichlorophenoxy-ethyl-sulphate may give satisfactory weed control only with the first application, and that the efficacy of successive treatments after short time intervals may be reduced to a very low level by the development of a population of detoxicating soil micro-organisms.

A solution of 100 p.p.m. 2,4-dichlorophenoxyacetic acid perfused at thirty days was afterwards detoxicated with only a slight lag of about two days, and the maximum rate of disappearance of toxicity was of the same order as that for the first perfusion with dichlorophenoxy-ethyl-sulphate. This means that the detoxicating soil organisms are definitely adapted to 2,4-dichlorophenoxyacetic acid, and this is further indication that the latter was itself the adapting molecule.

Lastly, samples of perfusate were taken during the first dichlorophenoxy-ethyl-sulphate perfusion and run on a one-way paper-partition chromatogram using propanol – ammonia as the developing solvent. The position of the spots of the phytotoxic compound were afterwards determined by sectioning the paper strip and subjecting these sections to a sensitive biological assay. Full details of this assay will be published later. The R_F value of the toxic compound generated from sodium 2,4-dichlorophenoxy-ethyl-sulphate was 0·7, which is identical with that given by 2,4-dichlorophenoxyacetic acid samples run from a fresh solution and also after prior perfusions through soil. Samples of dichlorophenoxy-ethyl-sulphate perfusate have been analysed during the whole of the perfusion period before detoxication sets in, and there is no indication that more than one toxic compound is generated.

There seems little doubt, therefore, that the toxic molecule is indeed 2,4-dichlorophenoxyacetic acid, and that it afterwards behaves in the same way as if added directly to the soil.

I wish to express my thanks to Dr. W. G. Templeman, of Imperial Chemical Industries, Ltd., for supplying me with the sodium 2,4-dichlorophenoxy-ethyl-sulphate, and also to Miss R. F. Thresh, of this Department, for carrying out the chromatogram analyses and the associated biological assays.

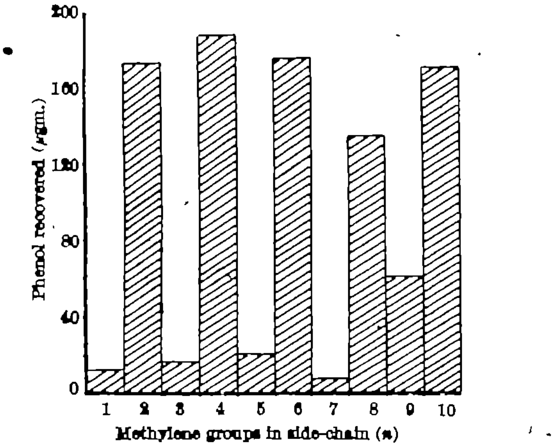
β-Oxidation of ω-Phenoxyalkylcarboxylic Acids in the Flax Plant

SINCE the classical work of Knoop[1] on the β-oxidation of long-chain fatty acids within the animal body, numerous investigations have been carried out in this field. It is now established that such an oxidative mechanism does, in fact, operate in the animal[2]. On the other hand, evidence that β-oxidation occurs within plant tissue is lacking. Synerholm and Zimmerman[3], however, studying a homologous series of seven ω-(2 : 4-dichlorophenoxy)-alkylcarboxylic acids, found an alternation in growth-regulating activity to occur with increasing length of side-chain. The results were consistent with the view that degradation of these acids by β-oxidation was taking place within the plant.

We have synthesized the series of ω-phenoxyalkylcarboxylic acids ($C_6H_5O(CH_2)_nCOOH$) from $n = 1$ to $n = 10$ and have studied their influence on plant growth. These biological results will be discussed elsewhere. Breakdown of the acids within growing flax seedlings has also been investigated, the whole series being included in each of five experiments. The solution of the ammonium salt of the acid ($2 \cdot 5 \times 10^{-3}$ *M*) was supplied through the roots to a uniform group of 200 seedlings during ten days growth in the glasshouse. The seedlings were then washed, macerated with water and the acidified mixture steam-distilled under standardized conditions. Phenol was estimated colorimetrically in the steam

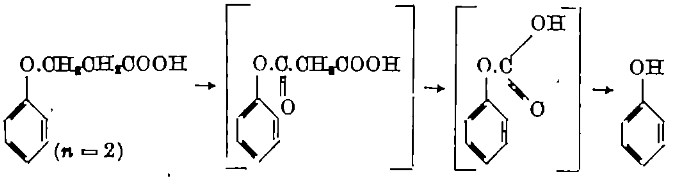


Phenol recovered from 200 flax seedlings following absorption of ω-phenoxyalkylcarboxylic acids ($C_6H_5O(CH_2)_nCOOH$) through the roots (average results from five experiments)

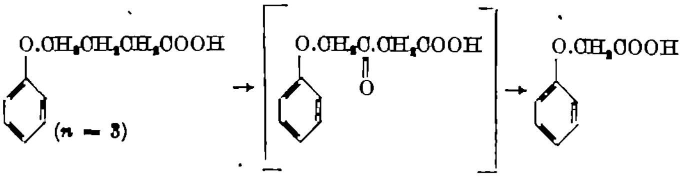
distillate[4]. No phenol was obtained from the compounds in absence of plant material following such treatment. Within the plant, acids with an even number of side-chain methylene groups gave rise to considerable amounts of phenol. No evidence is available on the form in which this phenol existed in the plant. From those acids in which n is an odd number only traces of phenol were obtained.

The results (see histogram) are consistent with the view that β-oxidation of the side-chain takes place as follows[3,5]:

(a)



(b)



Higher homologues might similarly be expected to suffer either repeated or alternating β-oxidation to yield phenol or phenoxyacetic acid. On this basis 9-phenoxynonane-1-carboxylic acid ($n = 9$) was not expected to yield phenol. In fact, in all five separate experiments appreciable phenol was produced. This apparently anomalous result, however, is of interest in connexion with certain animal metabolism studies, for example, the breakdown of β-hydroxyaliphatic acids in pigeon muscle[6], and of saturated triglycerides in human metabolism[7]. In both these investigations the compounds corresponding in chain-length to our phenoxy acids with $n = 8$, 9 and 10 showed different behaviour from the other homologues. These differences were ascribed to the occurrence of ω-oxidation[6,7], a mechanism which on spatial considerations would appear to be restricted to acids of these chain-lengths[2].

This chemical method for investigating degradation of phenoxy acids within living plant tissue is now being extended to the study of fungi and bacteria. In addition, further work involving enzyme preparations from the flax plant is in progress.

Hydrolysis and Metabolism by Soil Bacteria of Benzoyl Derivatives of D- and L-Forms of some Amino-acids

In a previous communication[1] we have reported that two strains (*KT* 83 and *KT* 82) of soil bacteria were able to utilize benzoyl-D-phenylalanine as well as benzoyl-L-phenylalanine as a sole source of carbon and nitrogen, whereas one strain (*KT* 84) could utilize the L-form but not the D-form, and that benzoyl-D-phenylalanine was hydrolysed by a suspension of either *KT* 83 or *KT* 82, but not by *KT* 84.

We have now studied the hydrolysis and metabolism by *KT* 83 and *KT* 84 of benzoyl derivatives of D- and L-isomers of six amino-acids, phenylalanine, tyrosine, alanine, aminobutyric acid, p-methoxyphenylalanine and 3,4-methylendioxyphenylalanine. At the outset we confirmed that *KT* 84 grew luxuriantly at 25° C. in the synthetic medium containing each one of the benzoyl derivatives of racemic forms of the above six amino-acids as a sole source of carbon and nitrogen, and could be transferred more than three times in succession.

The hydrolytic activity of the bacterial suspension *KT* 84 was then tested upon benzoyl derivatives of the racemic forms of six amino-acids in the presence of toluene, at 37° C. and at pH 7·0–7·2 for five days. We were able to isolate benzoic acid (95–82 per cent, calculated from the L-forms), benzoyl-D-amino-acids (90–80 per cent) and L-amino-acids, which were identified as the benzoyl compounds.

The properties of the compounds obtained in this way were as follow:

Benzoic acid, m.p. 119°–120°	
Benzoyl-D-phenylalanine, m.p. 139°–140°	$[\alpha]_D^{13} = -14{\cdot}9°$ (5·2 per cent in sodium hydroxide)
Benzoyl-L-phenylalanine, m.p. 139°–140°	$[\alpha]_D^{18} = +14{\cdot}8°$ (5·1 ,, ,, ,, ,, ,,)
Benzoyl-D-tyrosine, m.p. 162°–163°	$[\alpha]_D^{14} = -36{\cdot}2°$ (1 6 ,, ,, ,, ,, ,,)
Benzoyl-L-tyrosine, m.p. 162°–163°	$[\alpha]_D^{18} = +35{\cdot}9°$ (1·5 ,, ,, ,, ,, ,,)
Benzoyl-D-alanine, m p. 147°–148°	$[\alpha]_D^{11} = -37{\cdot}2°$ (2·5 ,, ,, ,, ,, ,,)
Benzoyl-L-alanine, m.p. 146°–147°	$[\alpha]_D^{11} = +37{\cdot}0°$ (2 5 ,, ,, ,, ,, ,,)
Benzoyl-D-aminobutyric acid, m.p. 110°–111°	$[\alpha]_D^{15} = -30{\cdot}2°$ (1·2 ,, ,, ,, ,, ,,)
Benzoyl-L-aminobutyric acid, m.p. 110°–111°	$[\alpha]_D^{18} = +30\ 4°$ (3:2 ,, ,, ,, ,, ,,)
Benzoyl-D-p-methoxyphenylalanine, m.p. 135°–136°	$[\alpha]_D^{16} = -\ 7{\cdot}0°$ (5·0 ,, ,, ,, ,, ,,)
Benzoyl-L-p-methoxyphenylalanine, m.p. 135°–136°	$[\alpha]_D^{8} = +\ 6{\cdot}9°$ (5·0 ,, ,, ,, ,, ,,)
Benzoyl-D-3,4-methylendioxyphenylalanine, m.p. 126°–127°	$[\alpha]_D^{13} = +\ 9{\cdot}8°$ (1·4 ,, ,, ,, ,, ,,)
Benzoyl-L-3,4-methylendioxyphenylalanine, m.p. 126°–127°	$[\alpha]_D^{13} = -\ 9{\cdot}7°$ (1 4 ,, ,, ,, ,, ,,)

It was further ascertained that none of six benzoyl D-amino-acids was hydrolysed by the suspension of *KT* 84 even after seven days. In a cultivation experiment, none of six benzoyl D-amino-acids but all six benzoyl L-amino-acids were utilized by *KT* 84.

KT 83 had the power to utilize in cultivation and to hydrolyse in the form of bacterial suspension six benzoyl-D-amino-acids as well as six benzoyl-L-amino-acids. Previously it was reported that the bacterial suspension *KT* 83 had hydrolysed only 34 per cent of benzoyl-D-phenylalanine at 37° during seven days[1]; but, in the present work, we observed that 87–85 per cent, calculated from the benzoic acid isolated, of six benzoyl D-amino-acids was hydrolysed within three days. It seemed that *KT* 83 had become adapted to the substrate during the successive cultivations.

Soil Bacteria and Chlamydospore Formation in *Fusarium solani*

CHLAMYDOSPORE formation and their numbers have been found to vary between species in the genus *Fusarium* and have been widely used in systematic nomenclature as a key character[1,2]. Nevertheless, no positive evidence has so far been adduced on the causes inducing the formation of this morphological structure, although it is generally presumed to be the result of unfavourable growth conditions. Control of soil-borne infection of various crop plants has been achieved by the addition of specific antibiotics[3] or by suspensions of soil bacteria and their toxins[4-6]. These observations, together with the more recent discovery[7] of plants absorbing antibiotics produced by soil micro-organisms, suggested the probability of this factor stimulating chlamydospore formation in *Fusarium* mycelia.

Two pure cultures of soil bacteria isolated from the black cotton soils of southern India, *B* I (not yet finally identified) and *B* II (*Bacillus licheniformis*), were employed in preliminary trials. Bacterial cells suspended in sterile distilled water were quantitatively added in seeding 2 per cent agar medium poured in Petri dishes. The bacterial-seeded and unseeded media (control) in Petri dishes were inoculated with a soil isolate of *Fusarium solani* and incubated for four days at 27°–29° C. Chlamydospore numbers in unit area were determined microscopically from uniform cork borer disks of the media cut in the centre of the colony surrounding the point of *Fusarium* inoculation (see table).

Both the bacterial isolates stimulated chlamydospore formation significantly. While 0·384 million cells of *B* I increased the number of chlamydospores over the control from 5 to 13, the corresponding figures in the case of *B* II were from 5 to 109. Number of chlamydospores from *A* to *B* to *C* to *D* to *E*, *seriatim*, increased approximately two-fold with each increase in the concentration of *B* I cells.

Series	*B* I		*B* II	
	No. of bacterial cells added (millions)	No. of chlamydospores formed per unit area	No. of bacterial cells added (millions)	No of chlamydospores formed per unit area
A	0·128	8	0·384	109
B	0·384	13	1·152	110
C	0·640	22	1·920	111
D	0·896	41	2·688	120
E	1·152	86	3·456	132
F	1·280	102	3·840	132
Control	—	5	—	5

C.D. at 1 per cent level = 0·4 C.D. at 1 per cent level = 9·0

F E D C B A CONT. *F E D C B A* CONT.

As to the *modus operandi* of bacterial stimulation of chlamydospore formation, it is probably due to antibiotics produced by the bacteria *in situ*, since in preliminary experiments even the addition of bacterial metabolites induced such stimulation in *F. solani*. These observations are of considerable interest, as many *Fusaria* are known to survive in soils under adverse conditions of microbial antagonism[8,9].

I thank Prof. T. S. Sadasivan for his suggestions and interest throughout the course of this work, and Dr. E. W. McCloy, of the London School of Hygiene and Tropical Medicine, for the identification of the bacterial culture.

Growth-Factor Requirements of *Pellicularia koleroga* Cooke in Pure Culture

A PURE culture (isolate 1) of *Pellicularia koleroga*[1] (*Corticium koleroga*) was isolated from the basidiospores found on *Coffea arabica* leaves, following well-known methods[2]. The fungus grew well on a number of agar media containing fresh extracts of potato, onion, carrot, oat, bean and malt, whereas its growth was very poor on a dextrose nitrate medium. However, when small quantities of malt, yeast, coffee leaf or fungal mat extracts were added to the dextrose nitrate medium, the fungus made good growth. A culture of this fungus obtained from the Centraalbureau voor Schimmelcultures, Baarn, Holland, also behaved similarly, and its growth was even slower. It was therefore felt that *Pellicularia koleroga* may have certain growth-factor requirements.

That many of the filamentous fungi show growth-factor deficiencies when synthetic media are used is well known[3,4]. Pure growth-factors were added singly to flasks containing 20 ml. synthetic medium prepared from analytical quality salts (composition : 2 gm. KNO_3, 1 gm. KH_2PO_4, 0·5 gm. $MgSO_4.7H_2O$, 20 gm. glucose or sucrose, 1 litre glass-distilled water).

The *p*H value of this medium was 5·2; all cultures were incubated for 30 days at 20°–22° C. Both with glucose and with sucrose, a negligible amount of growth was made in the control medium to which no growth-factor was added, and in the media receiving any one of the following: riboflavine, pyridoxine hydrochloride, *d*-pantothenic acid (as calcium salt), nicotinic acid, and *p*-aminobenzoic acid at rates of 250 μgm. per litre; inositol at a rate of 100 mgm. per litre. The responses to thiamine hydrochloride and to biotin, which varied with the carbohydrate source, are shown in the accompanying table.

MYCELIAL DRY WEIGHTS (mgm.)

	With glucose	With sucrose
Thiamine hydrochloride (250 μgm. per litre)	129·5	89·9
(+) Biotin (100 μgm. per litre)	negligible	59·7
Control (no growth-factor added)	negligible	negligible

A further investigation of these interesting effects of thiamine and biotin is in progress.

I am indebted to Prof. T. S. Sadasivan, for his help and guidance during the course of this work.

Influence of Mineral Nutrition on the Resin Content of the Hop Cone

THE influence of manuring on the resin content of the hop cone (strobile) has been the subject of a number of investigations. Doerell[1] concluded from German and Czecho-Slovakian experiments that the resin content rose when potassium and phosphorus were applied in excess of nitrogen, and more recently Zattler[2], in Germany, has stated that phosphorus has a beneficial effect on resin content, but that excess of potash, and especially of nitrogen, depresses the resins. The depressing effect of nitrogen has also been reported by Keller and Magee[3] in the United States.

Contrary results have, however, been found by other workers. In the Poperinghe district of Belgium, a detailed study of the chemical and physical composition of the soil and its influence on the resin content of the hop was made by de Koker, Verbelen and Van der Velde[4]; no relationship could be found. In England, Burgess[5], in a manurial trial carried out over a period of years, studied the effect of complete omission of nitrogen, phosphorus and potassium on hop growth. The yield of cones was markedly depressed by these treatments, and, in the case of nitrogen and potassium, the plants developed characteristic deficiency symptoms; samples of hop cones were taken from each treatment and from a plot receiving complete nitrogen–phosphorus–potassium manuring, but on analysis no appreciable difference in resin content was found which could be attributed to the manurial treatments.

In view of these conflicting results, and as part of a programme devoted to the study of the mineral nutrition of the hop now being carried out at Wye, the question is being further investigated.

In 1951, samples of cones were taken from a long-term factorial manuring experiment primarily designed to study the effect of different levels of nitrogen, phosphorus, potassium and magnesium on the yield of cones of the Fuggle hop. The samples were analysed for total soft resins and α-acid, and the β-fraction determined by difference. The results obtained are shown in the accompanying table, the figures representing the mean values for totals of sixteen plots.

Treatment		Resin content as per cent of oven-dry cones		
		α-Acid	β-Fraction	Total soft resins
Nitrogen (as N)	300 lb per acre	4·06	7·57	11·63
	400 ,, ,, ,,	4·09	7·46	11·54
Phosphorus (as P_2O_5)	200 ,, ,, ,,	4·15	7·55	11·70
	500 ,, ,, ,,	4·00	7·48	11·47
Potassium (as K_2O)	200 ,, ,, ,,	4·02	7·36	11·37
	400 ,, ,, ,,	4·13	7·67	11·80
Magnesium (as Mg)	28 ,, ,, ,,	4·01	7·40	11·43
	83 ,, ,, ,,	4·14	7·63	11·76

As will be seen from the table, the levels of nitrogen, phosphorus, potassium and magnesium applied to the plots differed widely; but the effect on resin content was negligible, none of the differences found being statistically significant.

Sand-culture experiments using the Fuggle variety were also carried out at Wye in 1951 to investigate the effect of nitrogen, phosphorus and potassium nutrition on resin production. As this was a pilot experiment, the nutrient-levels chosen were necessarily somewhat arbitrary, but they were selected to give wide differences in the levels of nitrogen, phosphorus and potassium as follows:

Nitrogen	50 p.p.m. and 500 p.p.m.
Phosphorus	10 p.p.m. and 200 p.p.m.
Potassium	25 p.p.m. and 500 p.p.m.

Under the low-potassium treatment, the hop plants produced no cones; but samples were taken from all the other treatments and these showed no appreciable differences in resin content with the exception of the high-phosphorus treatment; this produced cones which were low in resins, but which were abnormal in that they were small and underdeveloped.

To date, these experiments lend support to the earlier findings of Burgess and the Belgian workers that mineral nutrition has little influence on resin-production in the hop cone.

The experiments are being continued and will be reported in full elsewhere at a later date.

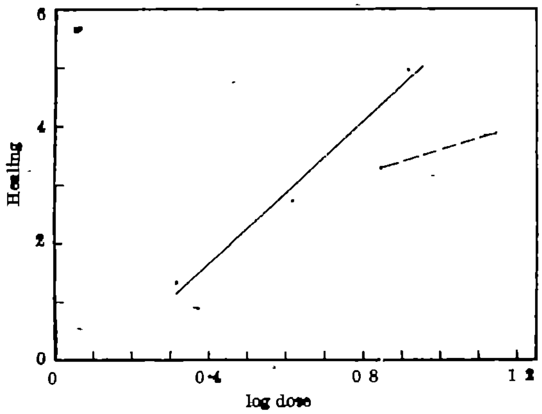
A Factor in Hay Inhibiting the Action of Vitamin D

During our investigation on the vitamin D content of hay in Holland, started in 1950, the impression soon arose that hay contains a factor antagonistic to vitamin D.

It was noticed repeatedly that the regression line, indicating the relation between recovery of rachitic rats and the logarithm of the dose of pure vitamin D, showed a higher—sometimes a substantially higher—regression coefficient than the analogous regression line of the fat from hay under examination (see graph). Doubling the dose of hay fat scarcely ever resulted in the recovery which would be anticipated from the initial dose applied.



———, Standard ; — — —, hay fat

Statistical calculation showed that the difference in slope of the lines for each individual experiment was not at all significant; in other words, the regression lines could be considered as running parallel.

As more experimental results became available, we were able to find out whether the two groups of regression coefficients indicated real differences. The results are summarised in Table 1. Only those experimental results have been inserted for which it could be assumed that they were on the straight part of the sigmoid curve indicating the relation between the log-dose and recovery.

Table 1

Exp. No.	Regression coefficient		Difference
	Standard	Hay fat	
1	3·87	1·46	− 2·41
6	6·12	1·99	− 4·13
7	5·31	2·99	− 2·32
	5·31	2·99	− 2·32
8	6·10	4·32	− 1·78
11	4·07	3·16	− 0·91
13	6·56	3·46	− 3·10
	6·56	7·65	+ 1·09
14	5·27	2·09	− 3·18

Mean difference, $\bar{d} = 2·12$; standard error, $s_{\bar{d}} = 0·50$; t(exp.) = 2·12/0·50 = 4·240; t(theor.) ($P = 0·01$) = 3·355.

It was evident from this that there was a highly significant difference between the regression coefficients of the standard and the hay-fat regression lines.

To prove in another way also that hay contains an anti-vitamin D substance, we have, from May to October 1951, added to hay fat definite quantities of vitamin D and investigated whether these could be recovered. We have noticed in the meantime that we have followed thereby the same course as Grant[1], and we arrived at exactly the same results.

During a fortnight, a few groups of eleven rats each were fed daily a quantity of hay fat, corresponding to 0·6 gm. of hay, contained in 0·2 c.c. of arachis oil. Other groups were given additionally 0·3 I.U. of vitamin D in the hay-fat solution. We were never able to recover the extra quantity of vitamin D supplied in that way. The quantity lost varied from 20 to 50 per cent. Neither was it recovered if the vitamin D and the hay fat were given separately at an interval of 8 hr., by supplying the vitamin D in the morning and the hay fat at night, and allowing the rats to take food during the day (Table 2). The inhibiting action of hay, therefore, cannot be attributed to a decreased absorption or destruction of vitamin D in the digestive tract, but is effective in the body after resorption from the gut.

Table 2

Exp. No.	Daily dose	X-ray healing	Vitamin D based on healing effect	Deficit (per cent)
10*A*	Fat of 0·6 gm. hay in 0·2 c.c. oil	1·56	1·98 I.U.	
	Fat of 0·6 gm. hay with 0·3 I.U. vit. D in 0·2 c.c.	3·32	5·28 ,,	21
10*B*	Fat of 0·6 gm. hay in 0·2 c.c. oil	2·80	3·96 ,,	
	Fat of 0·6 gm. hay with 0·3 I.U. vit. D in 0·2 c.c.	3·82	7·04 ,,	27
16	Hay fat in 0·2 c.c. oil	2·63	1·50 ,,	
	Hay fat with 0·4 I.U. vit. D given together	3·96	8·21 ,,	35
	Hay fat and 0·4 I.U. vit. D given separately	3·67	7·21 ,,	53

The antivitamin D factor (which we assume to be the same as that found by Grant) must be rather stable, as it has been found in hay as well as in dried grass. Furthermore, it is not only soluble in ether but also in petroleum-ether (b.p. 40–60° C.). The factor is resistant to saponification, as we could demonstrate it in the unsaponifiable fraction of hay fat.

The discovery of this factor inhibiting vitamin D may offer a partial explanation of the fact that some authors have not been able to find any vitamin D in fresh and artificially dried grass, whereas others could, and also of the unexplainable large differences in the vitamin D content sometimes noticeable in hay.

It is too early yet to offer an opinion on the importance of the anti-vitamin D factor as regards practical animal feeding. Our experiments with rats show in any event that the action of vitamin D can be diminished by 20–50 per cent by the factor. It is not at all certain that with cattle, for example, the effect will be exactly the same. That the existence of the factor can raise difficulties in practical feeding is clear from the observations on sheep recorded by Fitch[2] and Ewer[3] in New Zealand.

Corticium praticola Kotila; an Interesting Basidiomycete occurring in England

The usual forms of *Rhizoctonia* when grown on agar culture remain sterile, and are differentiated mainly on the basis of vegetative characters. During a study of the occurrence of *Rhizoctonia solani* Kuhn in England, a number of isolates falling within the limits of the form genus *Rhizoctonia* regarding vegetative characters formed basidiospores freely on agar cultures. These isolates were afterwards identified as *Corticium praticola* Kotila[1], although the measurements of basidia, sterigmata and spores were all slightly larger than those given by Kotila.

This is the first record of this fungus from Great Britain, and the first confirmatory record of Kotila's original work. D. P. Rogers[2], in dealing with the genus in 1943, failed to accept the species due to absence of original material and lack of confirmatory isolations.

The fungus was obtained from four widely separated localities in England. At Slough and Bristol, soil was very heavily infested with the organism, and at Cheshunt and Leeds it was found causing foot rot of cucumber and rot of dahlia petioles and leaves respectively. It is probably of common occurrence and may have been isolated previously not only in England but also in other countries and included under *R. solani*. As supporting evidence for this suggestion, isolates closely agreeing with the English ones have been obtained from several soils in South Australia during 1951. Although these isolates have not yet been induced to form basidiospores, they have been temporarily classified as *C. praticola*.

C. praticola differs from *R. solani* in its thinner hyphal diameter (6–9 μ, *C. praticola*; 8–12 μ, *R. solani*), faster growth-rate (0·55 mm. per hour, *C. praticola*; less than 0·5 mm. per hour, *R. solani*), and by the white mealy appearance of its mycelium later turning greyish-brown, in contrast to the felt-like cinnamon-brown of *R. solani*.

C. praticola is pathogenic to sugar beet seedlings above 15° C. and to a wide variety of hosts, including lettuce, tomato, cabbage and dahlia, at temperatures of 23°–25° C. and above. This fact, together with its vigorous saprophytic growth, makes it a potential danger, particularly if it becomes established in vegetable-growing areas. In South Australia the organism has caused severe losses of tomato seedlings being raised under warm conditions in nurseries.

As a laboratory organism, *C. praticola* is useful for teaching purposes. When grown on a soil extract agar with 0·1 per cent added sugar, the fruiting structures can be clearly demonstrated with little visual interference from sterile hyphæ. In view of its close similarity to *R. solani*, it may also prove a useful tool in aiding our understanding of the various isolates of *R. solani* and their relationship with *Corticium solani*.

The fungus was isolated while working in Prof. W. Brown's laboratory at the Imperial College of Science and Technology, London.

Isolation of Triploid *Saccharomyces cerevisiæ*

The production of tetraploids in a brewery yeast has been reported by Subramaniam and Krishna Murthy[1] and Mitra and Subramaniam[2], following treatment with acenaphthene and chrysene. These authors did not present genetic evidence to support their claim, which was based mainly on colony and other gross observations. Cytological evidence has recently been presented for a tetraploid with four chromosomes, derived from a "diploid two chromosome . . . strain"[3]. Tobias[4] studied a yeast isolated after acenaphthene treatment in terms of survival after X-irradiation, and concluded that the isolate was tetraploid. DeLong and Lindegren[5] have characterized certain strains of *Saccharomyces cerevisiæ* as triploid and tetraploid, based on the shapes of survival curves after ultra-violet irradiation. A paper by Lindegren and Lindegren[6] has recently appeared, describing the production of tetraploid yeast by crosses of diploids homozygous for complementary mating types. We wish to give a preliminary report on a procedure for the isolation of pure triploid clones of *S. cerevisiæ*.

A diploid clone was isolated (by the method of Pomper and Burkholder[7]) which required adenine and uracil for growth, that is, was homozygous for recessive alleles for adenine and uracil syntheses. This diploid was heterozygous for mating type (*a* and α of Lindegren and Lindegren[6]), and for genes involved in the syntheses of methionine and tryptophane. Haploid clones of both mating types, requiring methionine and tryptophane for growth (the same loci for which the diploid was heterozygous), were available to us. The diploid was mixed with both haploids (in separate tubes) by the 'mass mating' procedure of Lindegren and Lindegren[6]. After incubation for three days at 25° C., the cells were washed and plated on agar containing carbohydrate, nitrogen, vitamins and buffer, but lacking adenine, uracil, methionine and tryptophane. Under these conditions, neither the haploids nor the diploid should be able to grow, and, indeed, control plates had no colonies. However, a few colonies appeared on the plates from both 'crosses'. These were isolated as presumptive triploids. Since it was possible that we had merely isolated either doubly reverted diploids or haploids, it was necessary to carry out further tests to evaluate the assumption that these isolates were indeed triploids.

Neither the haploids nor the diploid employed in these crosses could themselves sporulate under ou test conditions. The observation that the 'triploid' isolates sporulated lent support to the belief that the test isolates were, at least, different from the origina components of the cross. Dissections were carried ou on asci from the 'triploids' arising from both crosses Examination of the mating-type behaviour of th ascospore isolates revealed that a number of them did not conjugate with tester stocks of either matin type.

In one ascus, two of the four spores mated and two did not. The latter pair were found t sporulate; the former did not. The sporulatin ascospores behaved as typical diploids and segregate for mating type, thus explaining the failure of th parental spores to mate. The conclusion appear justified that the parent culture had produced tw haploid and two diploid clones, and further, that th parent was probably a triploid or its nuclear equiv alent. Additional supporting evidence will be presented in a subsequent, more detailed, report. It should also be noted that tetraploids have been isolated by an analogous procedure.

It is a pleasure to acknowledge the assistance of Mrs. K. M. Daniels and Mrs. D. W. McKee. This work was performed under contract No. W-7405-eng for the Atomic Energy Commission.

Apparent Fumigant Action of Non-volatile Insecticides in African Huts

DURING the course of experiments conducted by one of us (G. D.[1]) on the residual action of various insecticidal preparations applied to the interior of native-type African houses, a pronounced fumigant-type action was found in houses treated with preparations of DDT and dieldrin.

Since then, tests have been done (G. F. B.) by filtering the air in a hut sprayed with dieldrin wettable powder five weeks previously. The apparatus used consisted of fumigant chambers made from 1-lb. glass jars fitted with waxed bungs. Air was removed from the top of the jar through a tube by means of a filter pump; fresh air entered through an upright funnel and was delivered at the bottom of the jar. The funnel had a screwed ring by means of which a disk of filter paper cut to size could be firmly stretched over the mouth of the funnel. The whole apparatus was sealed with paraffin wax. To reduce control mortalities, the jars were lined with a rough-surfaced paper and a piece of moist cotton-wool was put in the jar, the air passing over this as it was delivered. The jars were also covered with a dark cloth. Owing to a breakage in transit, the control could not be run at the same time as the test, and was carried out separately in the field laboratory.

Air was sucked through the single jar at 90 litres/hr. for forty minutes, and as a filter one thickness of Whatman No. 1 filter paper used. The house to be tested had been sprayed five weeks before (November 26, 1951) with dieldrin wettable powder to give an estimated deposit of 40 mgm. dieldrin per square foot.

Twenty to forty female *A. gambiae* and *A. funestus* mosquitoes were used in each test. Of the four trials carried out in the treated house, two were done with the funnel leaning against the wall in the darkest and the quietest corner, and two with the jar suspended just beneath the roof. In each of these positions one trial was made with the filter in position. The two other trials were done without filters; for the one near the wall, the filter-paper was simply removed, but when the jar was hung close to the roof the bung and funnel were taken off and the jar covered with mosquito gauze, the suction tube passing through this to the bottom of the jar.

Deaths 18 hours after exposure are given in the accompanying table.

		Number dead	Total	Percentage dead
Dieldrin with filter	(*a*) Wall	3*f*	9*g* + 5*f*	21
	(*b*) Roof	2*f*	8*g* + 22*f*	7
Dieldrin without filter	(*a*) Wall	2*g* + 21*f*	5*g* + 37*f*	55
	(*b*) Roof	2*g* + 23*f*	2*g* + 23*f*	100
Control		5*f*	5*g* + 29*f*	15

g = *A. gambiae*. *f* = *A. funestus*

Thus the apparent fumigant action is due to solid particles too large to pass the filter paper.

Further laboratory trials indicated that DDT and dieldrin wettable powders sprayed on to mud, plywood and glass all produce lethal particles. Thus an important source of such particles in a mud-walled hut may be the roof. However, mosquitoes caged close to the wall usually suffer higher mortalities than those suspended in the middle of the hut. The presence of lethal particles may help to explain why the efficacy of DDT insecticides on a practical scale, for example, against *A. gambiae* and *A. funestus* in Mauritius[2] and *A. darlingi* in British Guiana[3], has been greater than might be expected from laboratory and semi-field trials[4,5]. Insects activated to flight by contact with DDT[6] either on the substrata or as airborne particles would pick up more airborne particles in a given time than if they remained at rest[7]. Dr. G. Giglioli has recently informed us that in British Guiana he has been able to detect airborne particles of DDT for up to two years after spraying a house with non-absorbent walls.

There remains the question of any possible danger to health from these particles when those of the newer insecticides are breathed in for a period of years. The manufacturers of dieldrin now take a more optimistic view than they originally did of its toxicity to human beings (information supplied by the Shell Chemical Co. of Africa). DDT has already been used for many years without reported cases of ill-effects from inhaling drifting particles in houses. Dieldrin is applied at 20 per cent or less of the rate at which DDT is used. Unless it is correspondingly more toxic, the risk of using this exceptionally efficient preparation appears small.

Our thanks are due to the Colonial Insecticide Committee for permission to publish this note.

An Extended Orcinol Test Specific for Ketose Sugars

The formation of coloured products when sugars are heated with orcinol and mineral acids has long been known[1,2], and the reaction has been used for the detection and estimation of various sugars and related compounds. Thus Vasseur[3] states that the absorption curves for the products formed from pentoses, aldo- and keto-hexoses and methyl pentoses all differ from each other, but that the colours are not stable. According to Nozoe[4], the colours formed are due to the formation of furfural derivatives, and several pigments are formed successively, the final result being dependent on the acid concentration employed.

It has now been found that ketoses or ketose-containing sugars yield products which are soluble in aqueous alkalis with an intense orange-brown colour; by carrying out the reaction in the manner described below, it is possible to distinguish between ketoses and other sugars, and even between ketoses and keto-aldonic acids.

The most satisfactory procedure was found to be as follows: In a test-tube are mixed 5 c.c. of a 0·5 per cent solution of orcinol in *n*-butanol, 1 c.c. of concentrated hydrochloric acid and about 0·2 c.c. of a 5 per cent solution of the sugar to be examined. The mixture is heated to boiling, allowed to stand for five minutes and then diluted with 10 c.c. of water. The diluted mixture is shaken, allowed to separate into two layers and the upper butanol phase removed. The colour of the latter is noted; the butanol layer is then shaken with 10 c.c. of 4 per cent caustic soda solution, the mixture allowed to separate, and the colour of the two phases noted.

The colours obtained by this procedure, with various types of sugar, are given in the accompanying table.

Sugar	Type	Colour in acid butanol phase	Colour in alkaline butanol phase	Colour in alkaline aqueous phase
Xylose Arabinose	Aldopentose	Pale blue	Nil	Nil or very pale brown
Glucose Galactose Maltose Lactose	Aldose C_6 or C_{12}	Pale yellow	Nil or very pale yellow	Yellow
Fructose Sucrose Raffinose	Ketose or ketose-containing compound	Emerald green	Yellow with green fluorescence*	Deep orange-brown
2-Ketogluconic acid 5-Ketogluconic acid	Ketoaldonic acid	Nil Greenish-yellow	Nil Orange†	Nil Yellow-orange
Galacturonic acid	Uronic acid	Nil	Nil	Nil

* Aqueous phase much more strongly coloured than butanol phase.
† Aqueous phase less strongly coloured than butanol phase.

Since 5-hydroxymethylfurfural was found to give the same colour reactions as fructose, and furfural the same reactions as the pentoses, it seems probable that these aldehydes are intermediately involved in the test, as claimed by Nozoe[4]. In the case of 5-ketogluconic acid, 5-carboxyfurfural is the most probable intermediate, while with uronic acids and 2-ketogluconic acid the conditions of the test are not sufficiently drastic to effect their conversion into furfural.

I am indebted to Prof. L. F. Wiggins for his interest in this work.

A Sparing Effect by Formate or Methanol on the Impairment of Creatine Metabolism in Folic Acid Deficiency

In a recent communication[1] we reported on an involvement of dietary folic acid and vitamin B_{12} in creatine metabolism. The observations suggested that deficiencies of these vitamins were interfering with the economy of labile methyl groups. It has been established that the methyl groups of choline and methionine may undergo oxidative degradation to formate[2,3] and that the utilization of such metabolically derived formate for serine synthesis[4] and possibly in other single-carbon addition reactions such as nucleic acid formation[5] involves mediation of folic acid; this vitamin is also directly concerned with formate production from glycine[6]. It seemed possible, therefore, that the influence of folic acid on creatine formation might in part at least be due to a check on the drain of methyl to formate resulting in its increased availability for transmethylations (cf. ref. 6). A direct proof of this postulate was sought in the studies reported here on the influence by mass effect of administered formate on *in vitro* and *in vivo* creatine synthesis in mice suffering from folic-acid deficiency and in normal mice. Methanol was also used in place of formate since it functions better (see ref. 2) in the reverse step of formate reduction to methyl[2,3].

Twenty-four adult mice (inbred Swiss strain) were maintained on a folic acid-free purified ration[1] with 15 gamma per cent of vitamin B_{12} and 0·3 per cent iodinated casein. At the end of five weeks, when folic-acid deficiency could be inferred from observations on red and white cell counts and hæmoglobin contents, the animals were divided into groups of four (see table) receiving as supplements folic acid (10 gamma/mouse/day, orally) and sodium formate or methanol (1 mgm./mouse/day, intraperitoneally) with corresponding controls. Animals from each group were sacrificed at the end of 5, 8 and 9 days from the commencement of this grouping, for determinations of *in vitro* and *in vivo* creatine formation by earlier procedures[1]. The data for creatine

Group	Creatine		
	In vitro synthesis (γ per gm. of liver)	Per cent in wet muscle	In 24-hr. urine (mgm. per 100 gm. body-weight)
Basal diet (no folic acid)	116	0·257	1·57
Basal diet + formate	135	0·260	1·08
Basal diet + methanol	184	0·270	1·73
Basal diet + folic acid	203	0·288	1·80
Basal diet + folic acid + formate	210	0·293	1·80
Basal diet + folic acid + methanol	225	0·312	1·88

synthesis *in vitro* are exclusive of any Jaffe-reactive product that may have been formed from the added methionine by the D-amino-acid oxidase of the liver homogenates[7], since necessary controls[1] were run concurrently; creatine synthesis was further confirmed on paper chromatograms. Typical results are presented in the table and were essentially similar in the three periods of sampling.

It can be seen that the impairment in creatine metabolism brought about by folic-acid deficiency is partially restored by the administration of methanol; the effect due to formate is less pronounced. Similar results have been obtained in other studies on the N¹-methylation of nicotinamide[8].

The relatively less significant effect of methanol or formate supplementation in the groups receiving folic acid suggests that, if these compounds were functioning as methyl precursors, folic acid does not exert any direct effect on this synthetic step. This is in harmony with other observations (unpublished) on the probable direct non-participation of folic acid in methyl neogenesis from administered methanol and serine.

This work is supported by a grant from the Indian Council of Medical Research.

Response of the Vaginal Epithelium of the Ovariectomized Mouse to the Systemic and Local Administration of Œstrone

IN the ovariectomized mouse, vaginal cornification follows the administration of œstrogens systemically (for example, by subcutaneous injection), or locally by their direct application to the vaginal epithelium. However, the median effective dose for all 'true' œstrogens is considerably lower for the local method of administration than for the systemic method[1].

Histological and histochemical observations on the process of cornification elicited by the two routes of administration have been made. No qualitative differences were noted. Freud[2], in a similar investigation with rats, also failed to detect any differences. However, there are temporal differences in the onset of cornification, and also its duration, between the two methods of administration. Emmens[1] has already reported that cornification is attained about a day earlier with local administration. His observations were obtained in assays in which the doses used were not expected to produce cornification in all animals. The phenomenon has been reinvestigated using two dose-levels both of which were calculated to elicit a positive response in all animals.

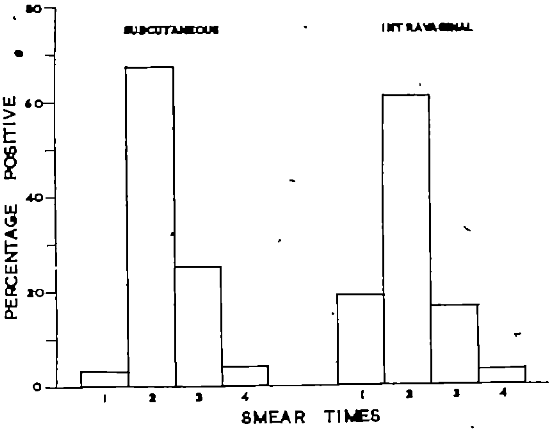
(1) *Onset of cornification.* 240 mice were used in two batches, the first of 95 and the second of 145. The mice were housed in boxes, five animals in each box. The boxes of each batch were divided at random into four approximately equal groups corresponding to the four experimental treatments shown in Table 1. Half the animals received œstrone in nut oil administered subcutaneously, and the remainder received œstrone in distilled water administered intravaginally. Two dose-levels were used for each route of administration (see Table 1). The lowest doses in each case are about 7–10 times the median effective doses reported elsewhere for this strain of mice[3]. A two-injection technique was used as described by Emmens[1]. Smears were taken night and morning, commencing the night after the second injection. The establishment of cornification was determined by the appearance of the first positive smear, that is, one consisting predominantly of cornified cells, and no leucocytes. Each smearing time was given a number to provide a basis for classification. The results from each experiment were combined and are shown in Table 1.

Table 1. TIME OF ESTABLISHMENT OF CORNIFICATION BY THE SUBCUTANEOUS AND INTRAVAGINAL METHOD, EACH AT TWO MAXIMAL DOSE-LEVELS OF ŒSTRONE

Smear time	Subcutaneous			Intravaginal		
	Low dose (0·5 µgm.)	High dose (2·5 µgm.)	Total	Low dose (0 005 µgm.)	High dose (0 025 µgm.)	Total
1	2	2	4	12	11	23
2	38	42	80	38	36	74
3	17	13	30	12	8	20
4	2	3	5	1	3	4

The results obtained with each route of administration were as follows: (i) *Subcutaneous.* Owing to the low group numbers at smearing times 1 and 4, adjacent groups must be combined for the statistical analysis. This gives a 2 × 2 contingency table. No statistically significant differences were found between the groups ($\chi^2_{[1]} = 0{\cdot}44$, $P > 0{\cdot}05$), showing that the dose-level makes no difference to the time of onset of cornification. (ii) *Intravaginal.* In this analysis the results from smearing times 3 and 4 were grouped, giving a 2 × 3 contingency table. No statistically significant differences were found between the groups ($\chi^2_{[2]} = 0{\cdot}06$, $P > 0{\cdot}05$), again showing that the dose-level makes no difference to the time of onset of cornification.

Since the dose-level was without influence on the time of cornification, the results for each method of administration were added together for each smearing time. This gives a 2 × 4 contingency table allowing a comparison to be made between each method of injection. The combined figures are given as marginal totals in Table 1. A statistically significant difference was found between the two methods ($\chi^2_{[3]} = 15{\cdot}70$, $0{\cdot}01 > P > 0{\cdot}001$). The results are illustrated graphically in the accompanying histogram. They show that the onset of cornification in the intravaginal method is approximately twelve hours in advance of the onset in the subcutaneous method. This confirms the finding of Emmens[1].



(2) *Duration of cornification.* Emmens[4] showed that the duration of cornification with the subcutaneous route of administration depends on the dose of œstrogen administered. The effect of dose on the duration of cornification in the intravaginal method has been investigated. Smears were taken from the intravaginal groups in the second batch of animals throughout the period of cornification. Table 2 shows the times when negative smears returned.

Table 2. Time of Reappearance of Negative Smears in the Animals Receiving Two Maximal Dose-levels of Œstrone Intravaginally

Smear time	Low dose	High dose
4	18	9
5	11	11
6	11	15

Although there might be a slight tendency for the effect of the high dose to persist for a longer period than the effect of the low dose, on statistical analysis no significant difference between the two distributions was detected ($\chi^2_{[1]} = 3·30$, $P > 0·05$). On the evidence available, therefore, there is no reason for supposing that dose-level influences the duration of cornification by the intravaginal method. However, it is possible that with wider dose intervals, such as those used by Emmens, differences in the duration of cornification would become apparent; this question requires further examination.

Two Forms of 1 : 2 : 3 : 5 Tetra-Acetyl D-Ribofuranose

In a recent communication, Davoll, Brown and Visser[1] have described two forms of 1 : 2 : 3 : 5 tetra-acetyl D-ribofuranose. The form first obtained had melting point 56°–58° and was probably identical with the compounds of Howard, Lythgoe and Todd[2], and of Bredereck and Hoepfner[3]. This substance changed spontaneously into another, melting point 85°, proved to be identical with the 1 : 2 : 3 : 5 tetra-acetyl D-ribofuranose of Zinner[4]. The transformation was reported to be accompanied by a change in specific rotation from $[\alpha]_D^{20} - 3·6°$ to $- 13·5°$ (in methanol).

Some time ago, I prepared this compound (using the method of Zinner[4]) in the lower-melting form (melting point 56·5°–57°). When a comparison with the higher-melting form (generously provided by Dr. Zinner, of Jena) was attempted, the whole of the material isomerized, and the form of melting point 56·5°–57° can no longer be prepared in this laboratory. This isomerization, however, proceeded without any significant change in specific rotation; $[\alpha]_D^{22}$ for the low-melting form $- 13·2 \pm 1°$; for the high-melting form $- 12·0 \pm 1°$ (both in chloroform). The case thus seems to be a simple (though very striking) one of dimorphism, and the speculations of Davoll *et al.*[1] regarding structural isomerism are probably unnecessary.

It would be of great interest, however, if workers in some laboratory uncontaminated with the higher-melting form would re-examine the transformation polarimetrically, since there is a definite contradiction between the results of Davoll *et al.*[1] and those I have obtained.

Disadvantages of Race Mixture

In the modified Unesco statement on the nature of race, issued at the Fourth International Anthropological Congress in Vienna on September 7, we find the incautious affirmation that "there is no evidence that race mixture produces disadvantageous results from a biological point of view". To cite a single case, there is recent evidence[1] that sickle-cell anæmia, a fatal disease, occurs with much higher frequency in American Negroes having some white ancestry than in African Negroes of pure descent, although the latter show a much higher frequency of the sicklæmia trait, which is without symptoms.

Similarly, the *Rh*-negative gene, which is responsible for the death of countless Caucasian infants and fœtuses, has been traced to prehistoric crossing between the Basques and peoples speaking the Indo-European languages. These crosses probably began at least as early as the Neolithic; but their effects on the death-rate of European infants and fœtuses (erythroblastosis) are still unabated. Here is ample evidence that race mixture can be disadvantageous in its racial effects.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 24

Society of Chemical Industry, Plastics and Polymer Group (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Discussion on "Polymer-Solvent Interaction".*

Chemical Society, Oxford Section (in the Physical Chemistry Laboratory, South Parks Road, Oxford), at 8.15 p.m.—Dr. D. A Dowden . "Industrial Catalysis" (Alembic Club Lecture). (All Fellows are invited)

Tuesday, November 25

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m —Mr. W. A. Allen and Mr. P. H. Parkin . "The Acoustic Design of Auditoria". (Further Lectures on December 2 and 9.)

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p m.—Dr. C. F. Hickling . "The Expansion of Fisheries in the Colonial Empire".

Society of Public Analysts and Other Analytical Chemists, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 6 p.m —Annual General Meeting ; at 6 30 p m —Papers on "Forensic Science".

Society of Instrument Technology (joint meeting with the Control Section, at Manson House, 26 Portland Place, London, W.1), at 6.30 p m —Symposium on "Control Valves".

Tuesday, November 25—Wednesday, November 26

Institution of Gas Engineers (at Church House, Westminster, London, S.W 1), at 10 a.m. each day —18th Autumn Research Meeting

Wednesday, November 26

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2 30 p m —Mr George F. Underhay : "Raw Materials for Paper".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers (joint meeting of the Supply and Measurements Sections, at Savoy Place, Victoria Embankment, London, W.C.2), at 5 30 p.m —Mr. D. McDonald . "The Electrolytic Analogue in the Design of High-Voltage Power Transformers" . Dr. K F Sander and Mr. J. G. Yates : "The Accurate Mapping of Electric Fields with an Electrolytic Tank".

Illuminating Engineering Society (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m —Discussion on "Home Lighting".

Society of Chemical Industry, London Section (joint meeting with the Food Group, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 30 p.m.—Rt. Hon. the Earl of Halsbury : "Science, Industry and Society".

Wednesday, November 26—Thursday, November 27

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1), at 10 a m. each day.—Autumn General Meeting.

Thursday, November 27

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p m.—Prof. S. E. Hollingworth "Hunting Sulphur in the Andes".*

University of London (at the Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5), at 3 p.m.—Prof. J Elkes : "Some Uses and Limitations of Pharmacological Method in Psychiatric Research".*

University of London (in the Chemistry Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. N. F. Mott, F.R.S. "Dislocations and the Properties of Solids".* (Further Lectures on December 4 and 11.)

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S W.1), at 6 p.m. —Colonel H. T. Jessop : "Photoelasticity and Aircraft Research".

Friday, November 28

Physical Society (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Presentation of the 29th Duddell Medal and Prize to Mr. C. Waller, and the presentation of the 8th Charles Vernon Boys Prize to Dr. B. Bleaney ; Mr. C. Waller : "Some Topics concerning the Production and Application of Nuclear Emulsions" ; Dr. B. Bleaney : "Paramagnetic Resonance at Low Temperatures".*

Institution of Mechanical Engineers (at Storey's Gate, St James's Park, London, S.W.1), at 5.30 p.m.—Mr. Herbert Addison "Instruction and Research in Hydraulic Laboratories".

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p.m —Dr. Derek J. Price . "Chaucer's Astronomy".

Saturday, November 29

Botanical Society of the British Isles (at the British Museum (Natural History), Cromwell Road, London, S.W.7), at 2.30 p.m.—Annual Exhibition Meeting.

British Psychological Society, Scottish Branch (in the Psychological Laboratory, 12 University Gardens, Glasgow), at 2.30 p m.—Dr. Sarah S McIntyre : "A Study of National Prejudices" · Mr. John H. Chaplin and Mr. Robert C. Vallance · "Scientific Curiosity and Interest in relation to Ability and Achievement in School".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned .

Lecturer in Mathematics (preferably with a good honours degree and able to take lectures to honours degree standard)—The Registrar, Technical College, Sunderland (November 29).

Assistant Teacher (Grade B) in Botany—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (December 1).

Censor and Tutor in Science in University College and Part-time Lecturer in the University—The Secretary, The University, 38 North Bailey, Durham (December 1)

Lecturer in Mechanical Engineering, and an Assistant (Grade B) in Engineering, at Constantine Technical College—The Director of Education, Woodlands Road, Middlesbrough (December 5)

Junior Observer (with a good honours degree in astronomy, physics or mathematics)—The Director, The Observatories, Cambridge (December 6).

Scientist (with a degree in engineering and M.I.M E.) to take charge of a group responsible for applying the results of scientific research to the design of experimental machines in connexion with the underground mining of coal (Ref. TT/506), and a Scientist, Grade II (preferably with a good geological background) to assist in research on basic underground mining processes involving the structure and physical properties of coal measure rocks (Ref. TT/507), at the Central Research Establishment, Isleworth, Middx—The National Coal Board Establishments (Personnel), Hobart House, Grosvenor Place, London S.W.1, quoting the appropriate Ref. No. (December 8).

Senior Lecturer or Lecturer in Mathematics at Fourah Bay College, Sierra Leone (University of Durham)—The Secretary Advisory Committee on Colonial Colleges, 15 Victoria Street London, S.W.1 (December 8)

Established Geologist in the Geological Survey—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (December 9).

Senior Geophysicist in the Bureau of Mineral Resources, Geology and Geophysics, Melbourne, principally to edit and attend to publication of geophysical reports, maps and plans , also to supervise the work of the drafting and library staffs—The Deputy High Commissioner, Australia House, Strand, London, W C 2, endorsed for attention of 'The Senior Representative, Division of Industrial Development' (December 11)

Assistant (with honours degree in biochemistry, agricultural chemistry, or equivalent qualifications) in Agricultural Biochemistry—The Secretary, The University, Aberdeen (December 12)

Assistant Lecturer in Chemistry—The Registrar, University College of North Staffordshire, Keele, Staffs (December 15)

Experimental Officer (woman, with a University degree with chemistry or microbiology as a principal subject, or equivalent qualification) in the Domestic Preservation Section—The Secretary, Long Ashton Research Station, Bristol (December 15)

Agricultural Economist and Assistant Agricultural Economists, at Newton Abbot—The Registrar, The University, Bristol 8 (December 29).

Lecturer in Electrical Engineering at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 31).

Lecturer in Biochemistry (graduate in medicine or science) at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C.1 (January 3).

Assistant Lecturer in Botany—The Registrar, The University, Manchester 13 (January 5)

Principal—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C 2 (January 10).

Reader in Social Anthropology at the Australian National University—The Administrative Officer in the U K , 27 Russell Square, London, W.C 1 (January 19).

Lecturer or Senior Lecturer in Botany at the University of Otago, Dunedin—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C 1 (January 30).

Scientific Assistant (Veterinary Officer) (M R C V.S or its equivalent and a knowledge of languages essential)—The Director, Commonwealth Bureau of Animal Health, Veterinary Laboratory New Haw, Weybridge, Surrey (January 31).

Professor and Head of the Department of Organic Chemistry, Professor and Head of the Department of Power Engineering Professor and Head of the Department of Chemical Technology and Chemical Engineering, and a Professor of Mechanical Engineering—The Registrar, Indian Institute of Science, Bangalore 3, India (February 1).

I.C.I. Research Fellowships in Biochemistry, Chemistry, Engineering, Pharmacology or Physics—The Secretary, The University, Edinburgh (February 28).

Assistant Lecturer (with an honours degree in agricultural chemistry, biochemistry or physiology) in Agricultural Chemistry at the School of Agriculture, Sutton Bonington—The Registrar The University, Nottingham

Assistant Lecturer (with an honours degree, and interested in the physical aspects of biochemistry) to teach Chemistry and Physics, and to co-operate in the research work of the Department—The Secretary, Royal Technical College, Glasgow

Biological Assistant (with a B.Sc. in either biology or physiology) in the Courtauld Institute of Biochemistry—The Secretary, Middlesex Hospital Medical School, London, W.1.

Chemist of B.Sc. (Special) standard, to take part in an investigation of urinary steroids in clinical cases—The Dean, Guy's Hospital Medical School, London Bridge, London, S.E.1.

Electrical Engineer for design work on large capacity 11 KV and LT factory installations, and for work associated with steam boiler plant, compressed air installations, cranes and machine tools—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, quoting 390.

Experimental Officers at R.A.F. Signals Establishments.—at Ruislip, for general experimental work and tests in connexion with design of radio communication and radar systems (three posts); at Medmenham, for installation design of airfield communications and landing aid systems, equipment investigations and siting problems (six posts), for design of installations for large radio receiving and transmitting stations (one post), for design of aerial and feeder systems (one post), for design, development or test of prototype mobile and portable radio and radar installations (six posts), for reconstruction of a radar landing aid and organization of associated experimental investigations (one post); at Watton, Norfolk, for development of highly specialized radio and radar equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.416/52A.

Head Statistician for the supervision of the Association's varied statistical and mathematical work, and carrying out and reporting on anthropometric work, field trials of footwear, etc., and a **Chemist** (young) and a **Physicist** (young) for work on footwear production and wear problems, and shoe materials and other products used in the industry—The Director, British Boot, Shoe and Allied Trades Research Association, Rockingham Road, Kettering, Northants.

Lecturer in Chemistry—The Acting Registrar, University College, Exeter.

Metallurgists to study problems in the casting, fabrication and joining of non-ferrous metals—The Research Manager, British Non-Ferrous Metals Research Association, 81–91 Euston Street, London, N.W.1.

Physical Chemist for research on surface activity and other phenomena related to detergents, etc. (ability to apply experimental results to practical wool scouring problems is of importance)—The Wool Industries Research Association, Torridon, Headingley, Leeds 6.

Physicist for work on physical problems related to biological effects of high energy neutrons—The Director, Radiobiological Research Establishment, Harwell, Didcot, Berks.

Research Assistants (with a degree in metallurgy or chemistry) to work on a study of slag inclusion in steels, or other agreed chemical or metallurgical problem—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Scientific Assistant (University degree in natural science and knowledge of languages essential)—The Director, Commonwealth Bureau of Animal Health, Weybridge, Surrey.

Senior Experimental Officer for development of calibration procedure for radio test equipment and preparation of calibration publications, and **Assistant Experimental Officers** for the calibration of transfer standards involving (*a*) frequency and pulse measurements or (*b*) bridge and miscellaneous measurements, at an R.A.F. Signals Experimental Establishment in Bedfordshire—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.415/52A.

Senior Scientific Officer at London headquarters of the Ministry of Supply, for the assessment of the performance of supersonic aircraft projects—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.296/52A.

A COMMONWEALTH INSTITUTE IN LONDON

It is clear from the Minister of Education's foreword to the report of the committee of inquiry into the Imperial Institute* that no immediate action on the report is contemplated by the Government. Mr. K. G. Bradley (see p. 912) has been appointed director in succession to Sir Harry Lindsay, who retires at the end of this year, and one of the new director's first tasks will be to consider, in consultation with the Board of Governors and with the Government, in the circumstances then prevailing, on what lines the Institute should be carried on. The Minister gives no indication as to whether the Government is prepared to accept the essential conclusion and recommendation of Lord Tweedsmuir's Committee that the aims and organisation of the Imperial Institute need drastic revision, in order to bring them into line with present-day conditions in the Commonwealth; and to reflect the recent transfer of responsibility for the Institute from the Board of Trade to the Ministry of Education, with its corollary that the major responsibility for financing the Institute must be assumed by the United Kingdom Government. The publication of the report should enable those immediately concerned to consider the proposals at leisure and to make appropriate representations in good time if necessary.

It will be remembered that when, in 1949, by Order in Council, the control of the Institute was transferred to the Ministry of Education and its purposes redefined on a mainly educational basis, the scientific and technical work of the Institute was transferred to the Colonial Office. The Institute accordingly no longer has the direct interest of the scientific worker or technologist which it formerly possessed, particularly during the period 1907–49. It is clear from this report, however, that in its adaptation to meet the new needs and conditions, the reconstituted Institute, particularly in its exhibitions in the galleries and in the cinema, and in its work as a centre for the dissemination of information and the discussion of problems relating to Commonwealth affairs, should continue to serve certain of their needs.

The Tweedsmuir Committee believes that the emphasis should shift from economic to social and cultural interests, and that the most important function the Institute could fulfil is to serve as a Commonwealth forum for the furtherance of mutual understanding among the members of Commonwealth countries by providing facilities for the presentation and exchange of ideas and information. To mark the change in outlook, it recommends that the name be changed to "Commonwealth Institute". To attain the new objective, it states that comprehensive reorganization of the exhibition galleries is necessary. The galleries, it is thought, should be divided into two main sections, one regional and national, the other illustrating the most important products and problems common to a number of

Commonwealth countries. Besides special displays in the entrance hall and elsewhere, and periodic exhibitions illustrating topics of current Commonwealth interest, there should also be development on the fine arts side and a considerable extension of the existing provision for cinema and related displays. Further, a programme department should be established to co-operate with the exhibitions and social staff of the Institute in a discriminating expansion of the programme of lectures, classes, conferences and projects for adults as well as for school children.

The lecture services contemplated here include extension of the travelling lecture scheme outside London in collaboration with the other agencies in this field, and, on the social side, provision of various amenities, including restaurant facilities, reference library and reading room, as well as the establishment of a social club for students and regular users of the Institute. Careful consideration has convinced the Committee that even when such well-sponsored plans like that for the International House for the University of London have been carried out and hostel accommodation also becomes available for all Commonwealth students through schemes concerted by the British Council with the support of the Colonial Office, the need will remain for a place or places where Commonwealth students can spend their leisure or carry on their wider studies, in comfortable and attractive surroundings. The reorganization of accommodation recommended by the Committee should also make possible the offering of accommodation and facilities for meetings and discussions to outside responsible groups concerned with Commonwealth problems.

The Committee's proposals are imaginative as well as practical; and while the Committee is convinced that the provision of social amenities on a generous scale is vital to the success of the plan that is proposed, the main argument for it, and for continuing the Institute, is the urgent need for attracting and enlisting the interest of the ordinary citizen in the Commonwealth and its affairs. For this reason, the greatly improved publicity which is listed as the last of the Committee's proposals may well be the most urgent, and some steps to develop this side may be imperative in order to obtain public support of the new proposals. Even as it is, the Committee has been disturbed by the widespread ignorance of the aims and intentions of the Imperial Institute. The execution of the Committee's plans will involve a considerable amount of goodwill and co-operation which will scarcely be secured without full understanding of their purpose and the reasons for the Committee's recommendations, which are virtually for a new Institute.

The proposals of the Committee involve strengthening the technical and administrative staff, with a consequent increase of about £12,000 in the salary bill: the longer opening hours, including Sundays, and the higher standard of cleanliness, which are recommended, also involve considerable additions to the number of attendants and cleaners, with a further increase estimated at £3,000. This estimate ignores any substantial economies in caretaking and general upkeep which may well accrue from the modernization of the building and equipment, nor does it take account of increased cost of heating, lighting, etc., due to the use of a larger area and the longer hours of opening. It is anticipated that a loss of income of approximately £13,000 through discontinuance of the present practice of letting accommodation, which the Committee strongly condemns, will be partly offset by receipts from persons or bodies who avail themselves of accommodation or facilities offered in accordance with the Committee's proposals.

The Tweedsmuir Committee's proposals thus envisage an increased contribution from the Government, which is put at no more than £15,000, but which might rise to £20,000–£25,000 per annum if the expectation regarding revenue proved unfounded. This is not a large sum for purposes such as the Committee indicates; but whether at the present time of financial stringency it will be forthcoming is doubtful, unless more imagination and foresight are shown than has marked post-war government intervention in Commonwealth affairs. There is also a matter of capital expenditure for which the Committee recommends an initial five-year programme. The modernization of the existing premises, some of the equipment of which is regarded as more appropriate for a museum of antiquities, will have to be put in hand in the near future, whoever may be the new occupants. Besides this, it is recommended that the re-conditioning of the entrance hall, the regrouping and reorganization of the galleries, the equipment of the Jehangir Hall, and the provision of amenities should be put in hand at the earliest possible date and completed within three years at the latest.

The Minister of Education's foreword to the report does not suggest that any urgency is attached to the matter by the Government; but it would not be right to infer from this that the comparatively small amount required to support so important a project will not be forthcoming. The proposals, however, in regard to accommodation may well involve major difficulties, for they require the return to the Institute, for use for its own purposes, of accommodation which has for long been in the hands of other bodies; and from its restrained criticism it is evident that the Committee is dubious as to the validity, let alone the desirability, of some of the arrangements made. The release by the University of London of the Central Entrance Hall and the Jehangir Hall is regarded as essential to the scheme, and could not wait on the re-building and re-organization already proposed when the University vacates the part of the premises it now occupies. Nevertheless, the Committee hopes that, in view of the amount of new accommodation acquired elsewhere by the University in recent years, it will regard with sympathy any request for re-adjustment of floor space, and that the whole of the west wing will revert to the Institute in the near future.

Finally, on the financial side, the Tweedsmuir Committee adds its own voice to those that in the past year or so have pleaded for some continuity of support for bodies engaged in research or in cultural and educational activities. Any system of grant to the new Commonwealth Institute should be placed on a quinquennial basis. The scheme advocated in this report will be prejudiced from the start if those responsible for its execution only know from year to year what amount of money they can count upon from official sources, and are limited to budgeting expenditure on a rigid annual basis. There is no surer means of ensuring waste of public money than to adopt such a practice where research, cultural and educational activities are concerned. Nothing will indicate more clearly the sincerity of its belief in the value of promoting Commonwealth understanding and relations than the way in which the Government responds to this particular recommendation of the Committee; and on its main thesis, should the Government decide not to adopt the scheme, a reasoned statement and no mere *non possumus* is demanded by this carefully argued report.

ATOMIC COLLISION PROCESSES

Electronic and Ionic Impact Phenomena

By Prof. H. S. W. Massey and E. H. S. Burhop. (International Series of Monographs on Physics.) Pp. xviii+670. (Oxford: Clarendon Press; London: Oxford University Press, 1952.) 70s. net.

In this volume, Prof. H. S. W. Massey and Dr. E. H. S. Burhop have provided an extremely complete compendium of results on the collisions of electrons and atoms. High-energy collisions and neutron collisions are deliberately omitted; but such problems as inter-atomic collisions, continuous X-ray production, and the collisions of electrons and atoms with solid surfaces are included, together with the more basic problems of the elastic and radiative collisions of electrons with atoms and molecules. The subjects are treated from an essentially experimental point of view, although considerable theoretical material is also included.

These topics were in the forefront of physical research in the 1920's and '30's. Indeed, a good deal of the material is that which did so much to help conventional spectroscopy to establish the quantum theory of atoms and atomic processes to its present state of completeness. Nowadays research on these subjects is out of fashion. We tend to think that if we took the trouble to work out the answers, we could explain the results of any fundamental atomic experiment. It is open to question whether such an attitude is sound. Among all the detail about the fundamental collision processes, not everything by any means has been satisfactorily explained. The book shows that there are a good many loose ends to be cleared up by some tidy-minded person. It will do a great service if such work is encouraged, for, in this field, good experimental work in atomic physics can be carried out comparatively cheaply. Such research is also an excellent training in accurate thinking on problems which are often basically simple.

I worked on electron collision problems in the late 1920's and early '30's, and it is a great pleasure to see work which I had almost forgotten (on the polarization of radiation excited in a gas at low pressure by a directed stream of electrons, and other problems of light-excitation) faithfully recorded in the volume. The work, though seeming elegant at the time, did not prove to be of any far-reaching importance, and is mentioned here merely as illustrating the by-ways into which the authors have strayed. In the context of the book, experiments of this type are seen in proper proportion as a part of the whole subject.

The work, besides presenting the fundamentals of a large part of atomic physics, also forms the basic raw material of applied work in gas discharges, in ionospheric problems and in astrophysics. The authors have been in the forefront of research in some of these subjects. This is probably the reason why they have taken the trouble to put all the scattered experimental results on collision problems into so comprehensive a form. Others may now have the benefit of their labours, and I am sure the book will be of great value to all those doing research in these applied fields. H. W. B. Skinner

THIRD EUROPEAN BREWERY CONVENTION

European Brewery Convention

Proceedings of the Congress, Brighton, 1951. Pp. x+352. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1951.) 45s.

It is the custom at the European Brewery Conventions to have one or more major themes for discussion: at the first Convention, which was held in Scheveningen, the subjects were of a general character; but at the second, which took place in Lucerne, the two highly important brewing problems of proteins in beer and the production of sterile beer by means other than pasteurization were the principal matters discussed. At the third Convention, which was held in Brighton in 1951 and the proceedings of which are here under review, the two main subjects chosen for discussion were: primary fermentation in the brewery, with special regard to the flocculation of yeast; and various aspects of the economic functioning of a brewery. The quality of the various papers read at Brighton was, on the whole, of a high standard, and some of the discussions animated and vigorous.

The subject of yeast flocculation is one of the utmost importance to brewers. In either top- or bottom-fermentation systems, unless a yeast is of a good flocculating type—that is, purges itself from the wort—the brewer may well be confronted with a number of harassing anxieties. This is especially the case with the brewing of draught beers with top-fermentation yeasts. If a yeast does not flocculate well, an unduly large and undesirable amount may be left in suspension in the beer, and thereby cause difficulty in fining and subsequent 'frets' in cask. So far as bottled ales are concerned, this question of yeast flocculation is not of such paramount importance, because the beer is submitted to a drastic process of filtration. Even so, when a poorly flocculating yeast is used for the fermentation of bottled beers, heavy 'bottoms' in the storage tanks can lead to serious losses.

The whole question of flocculation is bound up with the physical behaviour of a yeast in the fermentation vessel, whether the yeast be a top or bottom strain. Thus, a yeast which tends to come out of suspension rapidly is termed a flocculating yeast, whereas a yeast which separates slowly and tends to remain in suspension is called a non-flocculating or 'powdery' yeast.

The two most outstanding papers which were read in this part of the Convention were given by R. S. W. Thorne (Brewing Industry Research Foundation) and R. B. Gilliland (Arthur Guinness, Son, and Co., Ltd.), and it is difficult to do them adequate justice in a short review. Thorne, using the hybridization technique devised by Winge, showed that flocculation is under genetic control, having found that flocculation is dominant to non-flocculation. The genetic control of flocculence, however, is complex and, apparently, no less than three pairs of polymeric genes are concerned in the process, any one of which is sufficient to confer flocculence on a yeast which happens to possess it. Thorne claimed also that the genes controlling flocculence apparently mutate spontaneously at an astonishingly high rate to the non-flocculating type. Gilliland's contribution to this subject was more concerned with flocculence under brewery conditions, and he was able to distinguish four types of yeast isolated from a mixture used in top-fermentation brewing, which differ in various characteristics—for example, times of flocculation in worts. Gilliland claimed that a single gene segregation controls flocculence. There is, however, no real conflict between this observation and that of Thorne, because it may well be that these apparently conflicting results are due to differences that exist between different strains of yeast. On the other hand, there was a real difference of opinion between these two workers on the question of the incidence of mutation, Thorne holding the view that mutation is rapid and Gilliland that his strains are stable.

The foreign visitors to the Convention, which included such distinguished brewers and brewing chemists as Dr. B. D. Hartong (Holland), Prof. J. de Clerck (Belgium) and Dr. B. Trolle (Denmark), naturally enough discussed the question of yeast flocculence from the angle of bottom-yeast fermentations. Unfortunately, it has not proved possible up to the present time to hybridize bottom yeasts, and therefore the question of genetical control of flocculence in bottom-yeast strains has not been elucidated.

The economic functioning of a brewery forms no part of a review of this nature, but a number of interesting papers on miscellaneous subjects connected with brewing were also read. Two outstanding papers of general scientific interest were given in this section of the Convention. Prof. I. A. Preece (Edinburgh) dealt with the non-starchy polysaccharides of barley and their influence on wort composition, and Drs. G. Biserte and R. Scriban (France) discussed the proteins of worts. According to Preece, the bulk of these non-starchy polysaccharides are derived from the endosperm of the grain, and the proportion of cold-water soluble material obtained from barley appears to be a varietal character. Biserte and Scriban have made an elaborate study of the amino-acid and peptide fractions of wort, and have been able to separate by differential electrophoresis of the sodium chloride extracts of barley and malt a number of protein fractions which are also present in wort.

In conclusion, it can be said that this was a very good Convention indeed, and worthily maintained the high standard set by its two predecessors.

E. BARTON-WRIGHT

GMELIN'S HANDBOOK OF INORGANIC CHEMISTRY

Gmelins Handbuch der anorganischen Chemie

Achte völlig neue bearbeitete Auflage.

Herausgegeben vom Gmelin-Institut in Clausthal-Zellerfeld. System-Nummer 3: Sauerstoff. Lieferung 2, Vorkommen; Technologie. Pp. 83–300. 65 D. marks. Herausgegeben vom Gmelin-Institut fur anorganische Chemie und Grenzgebiete in der Max-Planck-Gesellschaft zur Forderung der Wissenschaften. System-Nummer 27: Magnesium. Teil A: Geschichtliches, Vorkommen, Bildung und Darstellung, Physikalische Eigenschaften, Elektrochemisches und chemisches Verhalten, Nachweis und Bestimmung, Legierungen; Lieferung 4: Legierungen von Magnesium mit Zink bis Rhenium, Oberflachenbehandlung. Pp. xiv+483–818. 100 D. marks. System-Nummer 41: Titan. Pp. xxii+481. 113 D. marks. System-Nummer 17: Arsen. Pp. xv+475. 140 D. marks.

(Weinheim/Bergstrasse: Verlag Chemie, G.m.b.H., 1951–52.)

THE steady progress in the publication of "Gmelin" is a praiseworthy and pleasing event. The work has proved of the very greatest value, and new volumes are always welcome. A detailed review here of such a work is impossible, and only a few main features of the parts named above can be sketched. This should not be regarded as minimizing its importance; but since the treatise is so well known and highly regarded, it seems superfluous to enlarge upon its merits.

The volume on oxygen, which deals with its occurrence and technology, includes the occurrence of free oxygen and ozone in the atmosphere at all levels, and the distribution of combined oxygen in the lithosphere. There is also a section on water from the same points of view. These will interest many kinds of readers besides chemists. The technological part deals not only with oxygen but also with ozone and with the purification of water and the production of hydrogen peroxide. Much patent literature is covered. The information on the technical production of pure hydrogen peroxide may be singled out for special mention.

The volume on magnesium alloys includes a long section on surface treatment. This field is of great technical importance; but a remark made in a previous review as to whether the completion of the purely chemical part of the book should be delayed by the issue of metallurgical and technical volumes may be repeated.

The volume on titanium, which is preceded by a portrait of Roger Adams and a dedication of the book to him in recognition of his timely support, deals with a subject of great present interest. Whether the claims made for the technical future of titanium will be justified, time alone can show; but to the chemist the volume, which appears to be complete, will be of great interest. The occurrence of the element, the preparation of the pure metal and its compounds, and details of their physical and chemical properties, are all covered to the end of 1949. The treatment is modern. The reader will perhaps be struck with the small space occupied by the descriptions of the chemical properties as compared with the physical, and this tendency should not be carried too far. A book on chemistry should lay special emphasis on the purely chemical aspects of its subject. On titanium monoxide, for example, there are five and a half pages on physics, including nearly three on spectra, and only nine lines on its chemistry. On titanium dioxide there are twenty pages on physical properties and only four on the chemical. The writers should see if they cannot find something more to say on chemistry.

The volume on arsenic is very detailed and complete. The sources are given fully, and as much space is given to some of little importance as to the main ones. Some attempt should be made to condense in such sections. There are eighty-three pages on occurrence, which is too lavish. A little more could have been said on the allotropic forms, although pages 116–122 are good so far as they go. The physical properties again occupy much more space than the chemical throughout, but the latter are given in more detail than in some other volumes. The hydrates of arsenic pentoxide are adequately considered. The action of light on arsenic disulphide is not sufficiently emphasized, and museum curators, for all they will find here, can still wonder why their specimens do not keep. Optical properties such as principal refractive indices and axial angles do not seem to be given where they might have been expected.

STUDIES OF SEVEN CENTRAL AFRICAN TRIBES

Seven Tribes of British Central Africa

Edited by Elizabeth Colson and Max Gluckman. (Published on behalf of the Rhodes–Livingstone Institute, Northern Rhodesia.) Pp. xx+410+28 plates. (London, New York and Cape Town: Oxford University Press, 1951.) 37*s*. 6*d*. net.

THE book consists of the following seven essays: Prof. H. M. Gluckman on the Lozi, Dr. E. Colson on the Plateau Tonga, Dr. Audrey Richards on the Bemba, Mr. J. A. Barnes on the Fort Jameson Ngoni, the late Godfrey Wilson on the Nyakyusa, Dr. J. C. Mitchell on the Yao, and Dr. J. F. Holleman on the Hera, Rowzi and Mbire of the Zezuru tribal cluster of central Mashonaland. The tribes are Central African in a vague geographical sense, and all speak Bantu.

"Our plan," the editors write in their preface, "was to produce a general description for each tribe which might be useful to officers working in the region and which could be used by students of anthropology who wished for some knowledge of the types of social organization to be found in the area." This collection of essays, which is intended to serve as a monument of the first eleven years of research planned and carried out by the Rhodes–Livingstone Institute, addresses itself primarily to two small groups of specialists and not to the general reader with sociological interests; the latter would find himself insufficiently equipped to deal with these, at times, severely technical essays in African tribal structure. As exceptions must be noted two essays which are slightly altered reprints of articles by Dr. Audrey Richards and the late Godfrey Wilson—the only essays which are not written by the Rhodes–Livingstone research team, and its successive leaders since the Institute's expansion. The editors must be congratulated on having departed from a programme of uniform presentation so far as to include these studies, the omission of which would have deprived the collection of its two fullest ethnographic accounts. Dr. Richards's essay (first published in 1935), in its admirable economy of exposition, is perhaps the best study of the Bemba, a tribe living on the plateau-land of north-eastern Rhodesia, to the study and description of which she has devoted many years.

By far the longest contribution is that of Prof. Gluckman on the Lozi, the ruling tribe of the Barotse nation (in the author's use of the two terms) of the Barotse Plain in North-western Rhodesia, a semi-pastoral group, who have marked cultural affinities both with the Southern Bantu and the peoples of the southern Congo basin, and who, living in the curious habitat of a Central African flood-plain, developed a very complex horticultural economy. The essay is divided into three chapters—Barotseland and the Barotse people (which includes class and tribal divisions); kingship, nation and land; and land, state, village and kinship—from which it can be seen how much the essay concentrates on the tribal political institutions. The centre of these is kingship, the main theme of the essay. Prof. Gluckman has written on several levels of analysis what surely is one of the most important sociological monographs on Bantu kingship.

Tonga as a linguistic term implies a main division of the zone of Central Bantu languages. Apart from the Ila- and Tonga-speaking population, "written material on any of these peoples is lacking". As in the case of the latter this material was scanty, information is very welcome. Dr. Colson, Prof. Gluckman's successor at the Institute, has selected for her research a part of these Tonga-speaking peoples, the Plateau Tonga, a population which has never formed a political group and which can be distinguished only in terms of their location and of the units of the present administration. They are one of the three matrilineal societies dealt with in this book, along with the Bemba and Yao. The description of the village unit is sketchy, that of the family and kin groups informative, and the analysis of the linking of matrilineal groups has many points of interest.

The Ngoni migrated north from Natal in 1820. Their state, of the type familiar from Zululand, was defeated by British forces in 1898, and this caused the decline of the central authority and of the regimental system, and some segmental autonomy. The breaking-up of political institutions, work on European farms and migrant labour are the background against which Mr. Barnes had to study Ngoni life. Dr. Mitchell's Yao, too, represent a "changing culture" in that sense. His investigation, that of the matrilineal system in particular, seems such a solid and imposing achievement that his book will be awaited with impatience.

Dr. Holleman's report on the Shona lacks the definiteness of the other contributions and might more suitably have appeared in a periodical. The report directs the reader's attention to the fact that little is known about this group of tribes, even on the ethnographic level to which the report keeps.

Each essay is followed by a most useful bibliography.

The collection is dedicated to Dr. Edwin W. Smith, co-author of the classic on the Ila-speaking peoples. The editors' few and dignified words of gratitude will be appreciated by all Africanists. The book seems worthy of bearing such a dedication.

F. B. STEINER

NEW STUDIES ON DEFECTIVE COLOUR VISION*

By Prof. W. D. WRIGHT

Technical Optics Section, Imperial College of Science and Technology, London

DURING the past few years, there has been a very lively interest in the subject of colour. This has derived in part from its increasing technical importance in the colour industries, while the introduction of the fluorescent lamp and the development of colour television have brought out new problems to be solved and new groups of scientific workers and engineers anxious to solve them. At the same time, there has been a great deal of interest in colour vision as a subject worthy of study in its own right, and speculation is still rife regarding the visual processes responsible for colour perception.

There is, unfortunately, plenty of room for speculation, since we are still ignorant of the visual mechanism by means of which an observer can distinguish one coloured light from another. When an image is focused on the retina, the reaction in the receptors must vary qualitatively when the wave-length of the light is changed; only thus can the brain receive signals which can be interpreted in terms of different colour sensations. It is generally believed that the characteristic messages to the brain originate in different types of receptor in the retina, one type being most sensitive to one part of the spectrum, another type to another part of the spectrum, and so on. The pattern of activity in the receptor types would then provide an effective means for differentiating one coloured stimulus from another.

So far, however, it has been impossible to complete this picture with objective information about the receptors. The three main methods of attack—histology, photochemistry and electrophysiology—have provided clear distinctions between the rods and the cones; but although Granit has recorded a variety of spectral sensitivity curves on various retinæ using a micro-electrode technique, it has not been possible so far to link these up with different photo-sensitive substances in the cones or with different cone structures. It is not impossible, as Willmer has suggested, that the division of the receptors into rods and cones may itself form the basis of a colour-discriminating mechanism; but the orthodox view is that colour perception is a purely cone function. We must hope that in due course the physiologists will be able to find ways and means of identifying different types of cone; but we have to recognize that their task is extraordinarily difficult and will require very refined techniques.

Since we are ignorant about the processes responsible for normal colour perception, we can scarcely hope to explain its abnormalities; but a curious position exists in that a great mass of quantitative data has been recorded on the characteristics of normal and defective colour-vision. In some respects, indeed, a very clear relationship has been established, and it is baffling not to be able to link this relationship to its physiological counterpart.

Various kinds of colour vision test can be carried out, and my own experience has been largely concerned with measurements made on a colorimeter in which two halves of the field of view are illuminated by monochromatic radiations selected from two spectra. In experiments on wave-length discrimination, for example, both fields are illuminated with single monochromatic lights of the same wave-length λ; one of the wave-lengths is then changed by a small amount $\Delta\lambda$ until a difference in hue can just be detected by the observer, the luminosities of the two beams having been kept equal. Or again, the sensitivity of the observer to lights of different wave-length can be tested by finding the energy $e\lambda$ required in one half of the field to produce a light sensation of constant magnitude as judged by making a luminosity match against a constant stimulus in the other half of the field, or by some other equivalent technique. In colour matching, one half of the field can be illuminated by a mixture of three monochromatic radiations taken from the red, green and blue parts of one of the spectra, and their proportions can be varied to give a colour match of the test colour in the other half of the field derived from the other spectrum.

Measurements of this type can take a considerable time and are unsuitable for the routine testing of large numbers of people; but they have the very great advantage that the light stimuli in the experiment are physically simple, and it is possible to study each variable of colour vision in turn.

When the results for those with normal and defective colour-vision are compared, one of the most important distinctions that is noticed is the relatively poor wave-length discrimination of the defectives. In an instrument in which the observer views a 2° field, the normal subject can distinguish some 150 different hues through the spectrum, whereas the defective may see only half this number or less, depending on the degree of his defect. This is not, however, due to a general lowering of colour discrimination, but to a reduction or total absence of discrimination in some parts of the spectrum, while in other regions discrimination is virtually unimpaired. Thus in the so-called red–green defect, radiations from the red–yellow–green spectral region may appear identical when luminosity differences are eliminated.

While poor colour-discrimination is perhaps the feature which is pre-eminently characteristic of defective colour-vision and is also the cause of most of the practical disabilities associated with the defect, other significant characteristics also emerge from experiments with a trichromatic colorimeter. The most striking is that, while a normal observer has to mix three radiations in order, in general, to make colour matches, it is found that some defective observers need to operate only two controls, while a very small number of persons exist who can do all their colour matching by operating a single photometric control. These three types of observer are known as trichromats, dichromats and monochromats respectively; and, while a considerable proportion of colour defectives have vision intermediate between dichromatism and normal trichromatism, it is with the dichromats that this article is especially concerned.

The natural explanation of these three forms of colour vision is that the normal retina possesses three kinds of colour receptor, the dichromatic retina two, and the monochromatic one. If one of the three receptors were inactive, we should expect that the dichromat would show an abnormal spectral sensitivity, and indeed in protanopia (the defect which is usually attributed to the absence of red receptors) the sensitivity curve is very low at the long-wave end of the spectrum. In deuteranopia, the sensitivity curve is very similar to the normal curve, and the defect can be explained on the assumption of a fusion of the red and green processes at some stage in the visual pathway from retina to brain.

---

* Substance of a Friday Evening Discourse given at the Royal Institution on May 2.

This explanation of these two forms of defect is supported by a more detailed study of the protanopic and deuteranopic colour confusions. The usual method of specifying a colour for a normal observer is based on the Maxwell colour triangle, which in its modern form has rectangular co-ordinates and is termed a chromaticity chart. A colour is specified in this chart by the proportions in which defined red, green and blue stimuli have to be mixed additively to match it; but for dichromatic vision the chart has one variable too many. Helmholtz investigated this subject theoretically and showed that, for an observer whose red receptors were missing, there should be a series of isochromatic zones across the colour triangle radiating from the red corner and that, for such an observer, all colours lying in a given zone would be confused, while colours from different zones would be distinguished. Many years later Pitt showed experimentally that the protanope confusion zones do radiate from a point in the red corner of the chromaticity chart, whereas the deuteranope zones are more nearly parallel, a result that provides some of the strongest evidence that the former defect is due to a missing red process and the latter to a red–green fusion.

Theoretically, various other forms of dichromatism might exist; but only a form in which the blue process is believed to be inactive, and to which the name of tritanopia has been given, has received much attention. A few cases of tritanopia have been reported in the literature, but, as they have usually been associated with some pathological condition of the eye, the existence of congenital tritanopia has been a matter of doubt. Certainly no data on tritanopia comparable to the information on protanopia and deuteranopia have been available.

I should, however, mention here that in a sense we are all tritanopes, since, for some reason not yet understood, small-field vision—that is, vision when viewing objects subtending 20′ arc or less and especially when imaged on the fovea—tends to become tritanopic. Some interesting data on small-field tritanopia have been recorded during the past few years, following the rediscovery by Willmer in 1944 of the phenomenon which had first been investigated by König fifty years earlier. Nevertheless, there is still great theoretical and practical interest in the investigation of congenital tritanopes, if such are to be found.

That was the position in May of last year, and if tritanopes were as rare as one in a million, as had been suggested, normal methods of testing were unlikely to produce many of them in any reasonable space of time. Unexpectedly, however, an opportunity for mass testing presented itself through an article on colour blindness which Mr. D. Wragge Morley was preparing for the magazine *Picture Post*. He intended to include some coloured reproductions of the well-known Ishihara charts which are widely used for detecting the red–green defect, and it happened that Lieut.-Commander D. Farnsworth, from the Medical Research Laboratory of the United States Naval Submarine Base, had in 1947 given me a chart designed on the same principles as the Ishihara charts but in colours that would demonstrate small-field tritanopia. It seemed that this chart might also serve to detect congenital tritanopia, and, at my suggestion, Mr. Morley kindly included a reproduction of it in his article.

Readers were invited to report any difficulty they had in reading the Farnsworth chart, and, out of a *Picture Post* readership said to be more than nine million, some nine hundred letters were received. As it turned out, these letters were in many cases from red–green defectives who were unable to read the ordinary Ishihara charts, while many more were from persons who were probably partial tritanopes. About forty, however, were from people who appeared to be genuine tritanopes.

The selection of the tritanopes was based partly on the way they described their reaction to the Farnsworth chart and partly on other evidence they supplied about their defect. For example, a number of the letters mentioned that, when playing the game of snooker, the writers tended to confuse the brown, green and red balls; these people were evidently red–green defectives. One correspondent, on the other hand, reported that he sometimes confused the blue and green balls and sometimes, too, the yellow and pink; these are just the confusions associated with tritanopia, and subsequent tests proved that he was, in fact, a tritanope.

For various reasons, in particular that of distance from London, not all the suspected tritanopes could make confirmatory tests in the laboratory, but seventeen cases were confirmed, and, of these, seven made a number of visits during the next few months for a series of observing sessions. Records were made of their curves of spectral sensitivity, colour mixture, wave-length discrimination and confusion loci in the chromaticity chart, the details being later published by the Optical Society of America (*J. Opt. Soc. Amer.*, 42, 509; 1952). The results confirm that tritanopes can do all their colour matching by the additive mixture of a red stimulus with either a green or a blue stimulus, wave-length discrimination disappears in the green to blue spectral region, and the colour-confusion zones tend to radiate from the blue corner of the chromaticity chart. All this is in agreement with the hypothesis that the defect is due to the absence of blue receptors, although the mean spectral sensitivity curve did not appear to be significantly lower than the normal at the short-wave end of the curve.

The incidence of tritanopia was evidently rather higher than one in a million; but, if an estimate were to be made, it was necessary to guess at the fraction of tritanopes who had bothered to reply to the article in *Picture Post*. After discussion with Mr. A. J. Burkart, of Hulton Research, I felt it was safe to assume that probably at least 5 per cent and at most 25 per cent of the tritanopes might have been expected to respond, which would put the incidence of tritanopia somewhere between 1 in 13,000 and 1 in 65,000. This is very much less than 2 per cent of red–green dichromats found among men and even the 0·12 per cent of women.

Another interesting feature was the proportion of men to women tritanopes, which worked out at 1·6 to 1·0, whereas in the red–green defect men outnumber women by 16 to 1·0. Here the large number of red-green defective correspondents were of value, for among them were 354 men and only 27 women, showing that the higher proportion of women tritanopes was not an artefact arising from any disinclination of men to write in and report on their vision. Evidently the transmission of tritanopia from one generation to another must differ from that for protanopia and deuteranopia.

I should like finally to refer to the social aspects of defective colour vision, since the very interesting correspondence which I had as a result of the *Picture Post* article confirmed that a real social problem exists. A few years ago the Physical Society Colour Group published a report on defective colour-vision in industry in which a survey was made of the occupations in which good colour-vision is necessary. If a colour-defective person enters such an occupation, he may later find himself barred from promotion or even relieved of his job altogether—a misfortune which could have been avoided by a pre-vocational test. The industries affected are not merely the colour industries, such as dyeing, paint and printing, but many others, like radio and electrical engineering, where colour codes are used extensively. Or again, in occupations such as agriculture and horticulture, the picking, and judging the quality, of tobacco, tomatoes, apples, cotton, bananas, etc., has been shown to need surprisingly good colour-vision.

My recent correspondence has re-emphasized the desirability of colour tests, not merely from the point of view of industrial efficiency, though this aspect should not be ignored, but rather as a form of vocational guidance to avoid personal distress and economic hardship. If testing of the colour-vision could be included as a regular item in the school medical inspection, as the Physical Society Report advocated, most of the difficulties could be anticipated and avoided.

Many people have been fascinated by the subject of colour, and since the basic problems of colour perception are still unsolved, its scientific attraction is likely to be maintained for a long time to come. Its social implications make its study even more worth while.

THE INTERNATIONAL COUNCIL FOR THE EXPLORATION OF THE SEA

By R. S. WIMPENNY
Fisheries Laboratory, Lowestoft

ON the twenty-fifth anniversary of the International Council for the Exploration of the Sea, the late Mr. H. G. Maurice, then in the mid-period of his long and lustrous presidency, said that the Council was a plant sown in Sweden, which had germinated in Norway and flowered in Denmark. It is therefore worth casting back to the origins of the distinguished and long-established international body which celebrated its jubilee early in October.

To begin with, it must be recalled that, throughout the 'eighties and 'nineties of the past century, there had been a great increase of fishing by the nations bordering the North Sea. Men like Thomas Huxley had earlier expressed views on the inexhaustibility of fish stocks, and these opinions were widely held. In spite of this, however, the fishermen working nearest the shore had reason to disagree, and their doubts were beginning to reach their Governments. It was, then, this feeling of the possibility and even likelihood of impoverishment of the North Sea that provided the convenient seed-bed for the flower referred to by Mr. Maurice.

The initial step in the Council's formation was taken by King Oscar II of Sweden, who called an international conference in Stockholm in June 1899 to consider international exploration of the Arctic, the North Sea and the Baltic, in the interests of the fisheries. Largely based on the King's suggestions, a programme dealing with hydrography, biology and the organization of a central bureau was agreed. At a further conference held in Christiania in May 1901, the Stockholm programme was confirmed and extended.

The first establishment took place at Copenhagen in July 1902, when Germany, the United Kingdom, Denmark, Finland, Norway, Holland, Sweden and Russia were the founder members. With the exception of Russia, all these countries are members to-day; but in addition there are France, Belgium, Spain, Portugal, Iceland and Ireland. The Council was constituted of two delegates from each country and an executive committee, called the 'Bureau', consisting of the president (Dr. W. Herwig), the vice-president (Dr. Otto Pettersen) and the secretary-general (Dr. P. P. C. Hoek). Nowadays, the Bureau has a 'first vice-president' and three other vice-presidents; otherwise the constitution remains much the same.

Under the Bureau at Copenhagen, there was appointed a hydrographical assistant, Dr. M. Knudsen, and a biological assistant, Dr. H. M. Kyle, while at Christiania there was set up a central laboratory under Prof. Fridtjof Nansen. The Christiania laboratory was to close down in 1907, but the post of hydrographic assistant continues to this day under Dr. J. Smed, successor to Dr. Knudsen.

The first working committees were three in number, one under the chairmanship of Prof. J. Hjort to study the migrations of fish, the second under Dr. W. Garstang to study the question of over-fishing, and a third under Dr. O. Nordqvist to study the biology of the Baltic. In the course of time, however, the increase in the area covered and the subjects investigated has brought about a considerable increase in these committees, so that at the last meeting there were in session sixteen committees and sub-committees, not to mention a steering committee called the Consultative Committee. This latter is composed of the chairmen of the other committees and was established after the First World War in order to secure an orderly arrangement of business at the Council's annual meeting.

From the start, or soon afterwards, the Council has been responsible for the issue of a number of publications. These were the series *Bulletin Hydrographique*, *Bulletin Statistique* and *Bulletin Planktonique*, *Publications de Circonstance* and *Rapports et Procès Verbaux*. The *Bulletin Planktonique* no longer appears, and the *Publications de Circonstance* were replaced in 1926 by the *Journal du Conseil*, but the remainder continue.

Between the date of foundation and the outbreak of the First World War was a period of great and well-integrated international effort in the North Sea. This consisted of regular hydrographic, plankton and trawling surveys of great descriptive value. The trawling work in particular resulted in a knowledge of the natural history of the plaice, to which little has been added since.

While up to that time no great advance had been made in our ideas on over-fishing, the confirmation that the European coastal grounds were nursery areas for plaice resulted in a proposal for their closure in the interests of the plaice fishery. A more striking result was the demonstration that young plaice from the coastal grounds grew up to three times as fast when transplanted to the Dogger Bank. Although there have been repeated demands for putting plaice transplantation into effect on a commercial scale, to make a substantial alteration to the fishery would involve doubling the population density on the Dogger Bank by moving about 15,000,000 small plaice. Up to the present, the practical difficulties of transport, particularly that of avoiding mortality in transport, have not been solved. Large-scale experiments have, however, been made by Denmark and are contemplated by Britain.

As there was no agreement on conservation by the closure of young plaice grounds between the two World Wars, the idea of sparing young fish by using larger meshes gained ground. A special meeting dealing with mesh experiments was held by the Council in 1934, and at another in 1932 an old argument against the conservation of young fish, which held that their removal produced a compensating greater growth of those that were left, was demolished.

Shortly before these meetings, Dr. E. S. Russell published in the *Journal du Conseil* a simple formulation of the factors responsible for the behaviour of an exploited fishery as they had been described by earlier workers. This was followed in 1935 by a more mathematical exposition of these factors by Mr. Michael Graham, who deduced that in the year in which he wrote the same yield could have been taken out of the North Sea by substantially less effort.

As a result of this and other work, international conventions to regulate the sea fisheries were drawn up in 1937 and 1946. Both recommended increased minimum sizes of the mesh for trawls and seines, and that of 1946 would doubtless have gone further had it been possible to give equivalents for the various and different offers of relaxations on fishing made by the different nations. In order to help to provide some of this necessary information, the Council arranged a special meeting in 1948 on the comparative efficiency of fishing vessels, their gear and parts of gear. Thereafter, a special sub-committee was set up to deal with the subject, and extensive and appropriate programmes were initiated, which are being carried out by several countries.

A part of the programme just mentioned involved under-water photography of trawls and seines, and one of the most important features of the Council's jubilee meeting in 1952 was the display of two films. One of these was from the Ministry of Agriculture and Fisheries and showed the behaviour of trawls under water near Malta. The other showed the behaviour of plaice about to be caught in the mouth of a Danish seine net used by the Fisheries Research Section of the Scottish Home Department in the shallow water of the Moray Firth.

Of more than sixty papers presented at this meeting, one of the most relevant to the Council's work was a contribution by Mr. R. J. H. Beverton on the principles of fishery regulation. This brought the mathematical formulation of rational fishing up to date with the inclusion of the post-war work of Beverton and Holt, and it is clear that more than a good guess as to how to obtain the biological optimum from the sea is now available. For the rest of the story of rational exploitation, shore economics and administrative policy will be responsible.

It is now quite clear that relaxations of fishing effort can be weighed and made equivalent, so that any proposals made by North Sea nations on the new Permanent Commission, designed to be set up as soon as the 1946 Convention is ratified, will be understood and transformable into the means of getting the same or a greater yield from the area with less effort.

There was much other material in the 1952 meeting which was in support of the main biological theme, but it is perhaps more profitable to notice that the greater part of the hydrographic contributions were offered to biological committees. This represents a desirable convergence between the long-established hydrographical and biological aims of the Council, which has become evident in the past few years.

In the early days hydrography had much of its own story to establish and describe; although, even then, the long-term cycles of the Baltic herring fishery were thought to have a direct hydrographic cause. However, as time went on, the relation with biology became closer and more obvious.

Slowly, in the period between the two World Wars, we had evidence of the warming up of the waters of the northern hemisphere, one of its consequences being the establishment of our great cod fishery in the Barents Sea, which only dates from 1928. Since the Second World War we have seen the cod spread and increase in Greenland waters so that, in the North Western Committee of the Council, Dr. Paul Hansen has been able to report that this species now breeds in west Greenland waters and does not rely on recruitment from Iceland.

It is with matters of this sort, and also in the detailed analysis of water movements, such as those responsible for the distribution of plaice eggs and young fish from their spawning grounds in the south-west North Sea to the nursery grounds on the Dutch, German and Danish coasts, that the hydrographers of the Council are at present engaged. They will doubtless have much similar work in the future, and there is no doubt that the series of synoptic charts of the monthly salinity, temperature and wind values for the waters of north-west Europe, which the Hydrographer of the Council took over from the Ministry of Agriculture and Fisheries at the last meeting, will be of great help to fisheries biologists.

Of special importance, however, will be the possibility of obtaining from the hydrographers information on winds, currents and temperatures which will enable fishery biologists to obtain not only forecasts of good fish broods and their distribution, but also the long-term prospects of a fishery.

Will the newly established Arctic fishing area continue to grow in extent, or have we to anticipate its recession ? What are the hydrographic conditions in the sea that govern the shoaling and migration of fish ? If we lose a commercial species in one area, can we find it again elsewhere or replace it by another ? These are the sort of questions related to hydrography to which we expect to see complete or partial answers given at future meetings of the Council, as well as the biological ones as to the behaviour of a stock of fish in relation to its degree of exploitability by man.

Most of the great names associated with the Council's inception are those of men who are now only memories; but it is happy to be able to record that Prof. H. H. Gran, who was responsible for much of the plankton work in the early days, was present at the jubilee meeting. The retiring president, Dr. K. A. Andersen, of Sweden, laid down his office as president after many years of close association with the Council's work.

The new president is Mr. A. T. A. Dobson, of the United Kingdom, and the new Bureau includes Prof. Jean le Gall (first vice-president, France), M. Lienesch (Holland), Prof. H. U. Sverdrup (Norway) and Dr. Vedel Tåning (Denmark). Mr. Michael Graham (United Kingdom), who resigned the chairmanship of the Consultative Committee for reasons of health, has been succeeded by Mr. R. S. Wimpenny (United Kingdom).

FOOT-AND-MOUTH DISEASE RESEARCH IN GREAT BRITAIN

An interim report on the research work carried out on foot-and-mouth disease at the Research Institute, Pirbright, has recently been published by the Agricultural Research Council*. The report deals only briefly with the many researches already done and the activities now in progress; this publication, however, is timely for, although some excellent scientific papers have been published from the Institute, they may not be available to the general public in Great Britain, who, naturally, are much interested in research work on foot-and-mouth disease. On this point the Lord President of the Council, in the foreword, says, "I have instructed that this Report be published and widely circulated in the hope that public interest may be informed and stimulated about a problem to which scientists are earnestly seeking a solution". We are promised a comprehensive report in the spring of 1953.

The position now held by the Pirbright Institute, the reliance placed on its work, the services rendered to other countries and the knowledge which is being built up, amply justify the existence of the Institute, which is generally conceded to be the most important centre in the world at which research work is carried out on this widespread disease. Mention may be made of only a few of the results of past and present work to justify this claim. It was at Pirbright that the complement-fixation test, now acknowledged widely as a reliable and rapid method of determining the immunological types of virus strains, was developed. Improvements have been made on the test to an extent that "it is now possible by this method to determine the type of virus involved, within a few hours of the receipt of material from a suspected outbreak". The value of this work cannot be overestimated, especially for countries in which a vaccination policy is in operation, for the vaccine to be used will depend upon the type of virus recovered from the infected animals. The occurrence of variant strains or sub-types of foot-and-mouth disease virus was established at Pirbright when the Institute was assisting a Mexican – U.S.A. Commission some years ago in studying the widespread outbreaks in Mexico. The control of the recent outbreaks of the disease in Europe has been made difficult by the appearance of variant strains which show significant differences when vaccination is being considered. It was at Pirbright that carefully controlled experiments on cattle showed that vaccine produced from virus cultured in tongues of healthy cattle slaughtered for food produced results as satisfactory as those with vaccine prepared from virus obtained from the tongues of cattle artificially infected with the virus. Although this more recent method of preparing vaccine was not worked out at Pirbright, but in Holland, it was the workers at the Pirbright Institute, using the facilities there, who showed quite definitely the value of the vaccine. This method obviates to a large extent the use of living cattle, and thereby results in a very considerable reduction in the costs of vaccine production.

The Pirbright Institute holds stocks of freeze-dried, diagnostic and typing sera and sends them on request to any country; since 1949 the income from the sale of these sera has been 10,000 dollars. The provision of such sera is an important part of the Institute's work. They are not easily produced, and their value to a country for purposes of diagnosis is great. In addition, it is possible by the use of reliable sera to differentiate not only between types and strains of foot-and-mouth disease virus, but also between these viruses and the agents causing diseases presenting somewhat similar clinical symptoms. It was, for example, by using Pirbright methods and sera produced there that a recent outbreak of disease in Canada was shown to be foot-and-mouth disease and not vesicular stomatitis, as was originally suspected.

Work on the preparation of vaccines for the prevention of foot-and-mouth disease is also carried out at Pirbright. In all, 135 vaccines have been prepared there during the past ten years, by eight different methods. Although vaccination is not practised in Great Britain, any improvement on foot-and-mouth disease vaccines is of value and interest to other countries. The more efficient the vaccine, the better will be the control of the disease in countries which adopt a vaccination policy, and, therefore, the reduction of the risk of infection being introduced from them into Great Britain. It is of much interest to note that, from experiments at Pirbright, it can now be said that "Present evidence suggests that full protection could be given for about four months. After this period an increasing proportion of vaccinated animals would become susceptible to the disease".

A finding of much practical importance by the Pirbright workers concerns the survival of the virus in meat and offal. Precise experiments have shown that some early observations that infection in an affected animal was largely confined to bone marrow have had to be revised, for "there is an equal risk of other tissues, including the lymph nodes, blood in the large vessels, liver, kidneys and the rumen, remaining infective for long periods". The significance of these findings is of the greatest importance to countries which import meat and offal from areas in the world in which the disease is endemic.

The latest research work at Pirbright is the use of unweaned mice as experimental animals in the study of these viruses. Their use will obviate to a large degree the need for using cattle in some of the work.

---

* Agricultural Research Council. Foot-and-Mouth Disease Research Interim Report. Pp. iv+12. (London: H.M. Stationery Office, 1952.) 6d. net.

Foot-and-mouth disease research can be carried out successfully only in a country relatively free from the disease and under elaborate conditions of isolation. Pirbright is ideally situated for this purpose. The results fully justify the existence of the Institute, and it is encouraging to read that "a large expansion of the buildings and facilities is planned" and that "When the additional facilities are available, the staff will be strengthened and the number of animals used for experiments at one time can be increased, with a corresponding speeding up of all the investigations".

TECHNICAL AIDS IN ARCHÆOLOGY

FOLLOWING the practice adopted at Edinburgh in 1951, a session on "Technical Aids for Archæology" was organized by Section H (Anthropology and Archæology) of the British Association at the meeting this year in Belfast. Being on the opening morning of the sectional sessions, however, and held in duplicate with one on Irish archæology, attendance was disappointing.

Mr. G. F. Mitchell, Fellow and lecturer in Irish archæology at Trinity College, Dublin, spoke first on vegetational environmental studies. It is now generally accepted that the palæobotanist can be the archæologist's most valuable collaborator, giving him some chronological framework in earlier periods, and at all periods an insight into early man's environment. The classical work in this field in Denmark[1] has related the earliest appearance of plantain pollen in Neolithic levels in peaty deposits to the development of agriculture at that period, for plantain is a weed of cultivation. In Denmark also, the appearance of beech pollen at a *Grenz-horizont*, or recurrence surface, in the raised bogs demonstrates a change in climatic conditions about 500 B.C.[2], and of rye and cornflower pollens at levels formed about A.D. 1200 indicates a change in agricultural activity[3]. In Ireland also, the rise of plantain pollen demonstrates the beginning of agriculture in Neolithic times, confirmed by the grain impressions on Neolithic pottery. There is also a well-marked recurrence surface, which, though not yet precisely datable in pollen terms, may lie at about 500 B.C.[4], although there is a second, higher surface, datable perhaps to about A.D. 400.

In evaluating climatic changes the natural sequence of pollen proportions is required, and this must be sought so far as possible from man's activities at that period, for these tended to destroy the natural woodlands and, in some places, produced heaths which invaded abandoned fields. Study of the ratio of herb to tree pollen makes possible some estimate of early agricultural activity, and the shrinking of forests may be traced as more skilled methods of agriculture were developed.

The seeds, charcoals and woods associated with early human activity show that the wood of all native trees was used in some way, that blackberries, elderberries, raspberries, strawberries and hazel-nuts were collected[5], that barley, oats, wheat and flax were cultivated, and that weeds were very abundant in prehistoric fields. The stomach of a Beaker period burial in the submerged clay of the Essex coast contained a pint of seeds, mostly blackberry[6], and in that of an Iron Age corpse recently found in a Danish bog seeds of pale persicaria, white goosefoot, corn spurry and black bindweed predominated. These plants were formerly cultivated, and, as they also occur in deposits of the early centuries of the Christian era in Ireland, they may have been cultivated for food there also.

Mr. E. M. Jope, lecturer in archæology in Queen's University, Belfast, spoke next on "History, Archæology and Petrology". During the past fifteen years the value of petrological examinations, especially of stone axes, has become fully appreciated by prehistorians. A number of axe factory sites are now known in the British Isles, and the petrologically determined distribution of their products is revealing wide, and sometimes unsuspected, contacts in Neolithic times. A lead was given by the Stone Axe Sub-Committee of the South-Western Group of Museums, which has published three reports[7], and a more general view is emerging as studies appear from other areas[8]. But the petrological demonstration that the Stonehenge 'bluestones' were brought from the Presely mountains in Pembrokeshire[9] nearly four thousand years ago still remains one of the most outstanding facts of British prehistory.

The study of building materials, particularly those in medieval buildings, can illuminate the economics and organization of the building trade; and as the material is bulky, when it is shown in use at a distance from its source reasonable transport facilities are implied, in many cases by road. Some valuable studies are already available[10], but the rate of such work is usually determined by the availability of reliable petrology, without which it is valueless, and much remains to be done in this field largely ignored by architectural historians. Some materials are, however, recognizable macroscopically with small chance of error, and systematic study of some of these is now showing the possibilities of this approach. Thus, Purbeck marble was extensively used throughout the civil zone of Britain in Roman times[11] and, after a lapse of about 750 years, was again even more extensively used throughout the Middle Ages. The marble industries of the Mediterranean area in Roman times are being studied at the British School at Rome[12]. Granite began to be commonly used in Devon and Cornwall churches during the fifteenth century, particularly as monolith arcade piers weighing often as much as five tons; and in a recent survey these have been found in nearly three hundred churches, some of them twenty miles or more from the granite outcrops, requiring land transport, in some documented instances by cart. The medieval export of blue slate from Wales[13], and from Cornwall and Devon[14], has also been studied. A survey of the medieval use of fine-quality building stone from the area of Great Oolite extending up the Cotswolds from Bath to Burford is now in progress, and it is already clear that such work can supplement surviving building accounts to give a more balanced estimate of the economic importance of such a stone industry[15].

An understanding of the variety of stones used for different purposes in historic buildings is of the utmost importance as basic data for the architects and others responsible for maintenance, if the buildings are to be preserved in a condition as near as possible to the designers' and builders' intentions[16]. This aspect has, in the past, been much neglected, as many historic buildings, particularly in Oxford, bear witness.

The third paper, by Mr. L. Biek, of the Ancient Monuments Laboratory, Ministry of Works, was on "Antiquities, Ancient Monuments and Research on Materials". In it he discussed first the relation between the scientific worker and the world's heritage of material culture[17]. A study of antiquities and ancient monuments by laboratory methods not only helps field archæologists by correlating the condition of finds with their environment, but also leads to better preservation and a fuller understanding and appreciation of objects by presenting them as nearly as possible in their original forms, as they were conceived by their makers. The benefits of such collaboration may, moreover, be mutual, for men of science working in some fields, such as corrosion studies, may gain a new insight into their own problems. Such work requires properly staffed laboratories which are specially intended for the problems involved[18].

Numerous illustrations of the results of such work, some with excellent coloured slides, were then given by Mr. Biek. Much new knowledge of early craftsmen's techniques comes from the detailed laboratory examination of their handiwork. Thus, the use of mercury in gilding sixth-century Merovingian brooches has been established, the mercury still being traceable microchemically. X-ray shadowgraphs have been invaluable in the study of antiquities, showing up even before cleaning, and without in any way altering the object, many details of their structure and decoration.

Recent studies in the Ancient Monuments Laboratory have shown that many of the rings used in making chain-mail of Roman times, found at Richborough, were punched out of cast sheet bronze. From a purely scientific point of view, the extreme fragility of similar rings, which must on internal evidence be taken to have been cold-worked, suggests that some ageing factor, as distinct from corrosion, may be operative under certain conditions. The survival on such rings of traces of suspension fibres (bast fibres, probably flax[20]) may possibly have been aided by the presence of corrosion products. But the most definite pointer of scientific interest provided by archæological finds was given by some excellently preserved iron objects of Roman and Saxon origin recently found at Hungate, York. Here research[21] showed that corrosion had been inhibited by phosphate and tannate, and the latter's suppression of sulphate-reducing bacteria was demonstrated for the first time. Such work is of potential value in the protection of present-day buried pipelines, for it has been estimated that the cost to England and Wales is £5 million a year due to corrosion losses in water mains alone.

Mr. Biek discussed the detailed collaboration of the laboratory staff with the archæologists in the field, not only on excavations but also in the study and preservation of buildings. Preservation of stonework has been much discussed in the past, and the study of masonry and brickwork in relation to their environment and the mortars used remains of greatest importance. It is also possible to learn something about early timberwork in buildings, and evidence of 'soft rot', a condition only recently recognized[22], has now been detected in the cavities left by bonding-timbers in the medieval masonry at Framlingham Castle, Suffolk. Apart from one very small piece of wood carrying this information, no trace of woody material was found in any of the several cavities, which originally contained timbers 15 ft. long by 1 ft. in diameter. In more modern buildings, the copper roof at Lancaster House and the century-old cast-iron tiles on the Houses of Parliament have recently been studied.

It is in the nature of things that references to such work should be widely scattered among many journals over a number of years, and only if there is direct systematic contact between archæologists and other scientists can the difficulties arising from such a state of affairs be reduced.

These three papers demonstrated selected aspects of collaboration between the natural sciences and archæology, and emphasized how the whole scope of inquiry into the past is being widened by this approach to the material. More laboratory facilities are required, such as are already operating at the British Museum, the Courtauld Institute, the Ministry of Works Ancient Monuments Branch, or Dr. H. Godwin's Sub-Department of Palæobotany at Cambridge, and in them workers are needed who by inclination are interested in archæological and historical problems as well as in those of the natural sciences. Neither are surely unreasonable requirements. It was encouraging to see that all three speakers at this session ranged widely in time, treating the study of material remains in both prehistoric and historic times as a continuum, and emphasizing what is generally accepted in classical studies, that in the Middle Ages, and even in more recent periods, a complete historical picture is not to be derived from written sources alone.

OBITUARIES

Prof. H. E. Roaf

WE regret to record the death of Herbert Eldon Roaf, professor emeritus in the University of Liverpool, on September 21 at the age of seventy-one.

Roaf was a Canadian who graduated at the University of Toronto and went to Liverpool to work under the direction of Benjamin Moore as Johnston Colonial Research Fellow. This early association with the famous biochemist is probably responsible for the interest in the chemical and physical aspects of physiology which Roaf sustained throughout his life, and which showed itself particularly in his earlier papers and in the work on biological chemistry which he published in 1921.

In 1906 Roaf was appointed assistant lecturer in the Department of Physiology under Sir Charles Sherrington, with whom he collaborated in research on the central nervous system. In 1911 he left Liverpool to become a lecturer in physiology at St. Mary's Hospital Medical School, London, and in 1920 was appointed to the chair of physiology at the London Hospital Medical College. He returned to Liverpool in 1932 as George Holt professor of physiology—a post which he held until his retirement in 1944. His chief interest in physiological research was colour vision, in which field he made many important contributions; but he was a man of wide and deep learning in his subject, and his "Text-book of Physiology" showed this clearly. He was a gentle, modest man, well loved by his colleagues and students, to whom he was devoted. During the War he undertook research on vision for the Admiralty, besides bearing a heavy burden of teaching and administrative work, in a department considerably denuded of staff.

He married Beatrice Sophie, daughter of Sir William Herdman, who survives him with two sons and two daughters.

Dr. William Brown

Dr. William Brown, founder of the Institute of Experimental Psychology in the University of Oxford, died in the early spring. Educated at Collyer's School, Horsham, at Christ Church, Oxford, and in Germany, he had a wide preparation for psychological work, having taken Mathematical Moderations, final honours in physiology, and Greats. He was John Locke Scholar in mental philosophy in 1908 and received his M.D. in 1918. In 1930 he was made a Fellow of the Royal College of Physicians. His first psychological work was done with Spearman at the University of London. This association produced what is now known as the Spearman–Brown formula, widely used in assessing the reliability of mental tests. In 1914 he was appointed reader in psychology at the University of London, which post he held until 1921. From 1921 until 1946 he was Wilde reader of mental philosophy at the University of Oxford, and during 1925–31 psychotherapist at King's College Hospital. In 1936 he became director of the Institute of Experimental Psychology at Oxford, which was founded with the assistance of a friend and patient of his.

Apart from his early work on the statistical treatment of mental measurement, which was of a high order, Dr. Brown's main achievement was, on one hand, to have brought about the recognition of experimental psychology at Oxford; on the other hand, his clinical work was unusually successful in that he obtained within the medical profession the reputation for meticulous care in excluding all physical causes before making a psychiatric diagnosis.

William Brown was very much interested in scientific societies. He was a member of the Mind Association, of the Royal Medico-Psychological Association and of the Royal Institute of Philosophy, and was president of Section J (Psychology) of the British Association for the Advancement of Science in 1927. He was president of the Society for the Study of Addiction, and associate foreign member of the Société Française de Psychologie. He had been a major in the R.A.M.C. during the First World War. Barely three months before his death, at the age of seventy-one, he delivered an astonishingly vigorous presidential address to the British Psychological Society.

NEWS and VIEWS

Nobel Prize for Physics, 1952

The Nobel Prize for Physics for 1952 has been awarded jointly to Prof. E. M. Purcell, of Harvard University, and Prof. Felix Bloch, of Stanford University, California.

Prof. E. M. Purcell

Prof. E. M. Purcell, who was born in 1912, graduated from Purdue University with a B.Sc. in 1933 and spent the succeeding year at the Technische Hochschule, Karlsruhe. In 1935 he went to Harvard, where he obtained his Ph.D., and joined the teaching staff as instructor in physics. During the Second World War he was associated with microwave work at the Massachusetts Institute of Technology. In 1945 he returned to the Lyman Laboratory of Physics at Harvard, and it was there that he made his discovery on magnetic absorption effects. Many physicists had been looking for dispersion or absorption effects of the magnetic properties of matter similar to those observed in the case of dielectrics, but it remained to Prof. Purcell to find the right conditions under which they manifest themselves. The first experiment was performed by putting a lump of paraffin wax contained in a resonant cavity into a magnetic field and observing the change of the Q-value when the magnetic field, H, passed through the resonance point ($h\nu = 2\mu H$). This absorption effect is very intimately connected with the mechanism by which the spin system transfers energy to the crystal lattice, a point which is very clearly emphasized in his first paper. The method is also of great sensitivity and has been used for measuring the proton magnetic moment of hydrogen gas. Since the first observation, many papers have been published by Prof. Purcell and others on details of great importance, such as line shapes and the use of the method for structural studies of crystals.

Prof. Felix Bloch

Prof. F. Bloch, who is professor of theoretical physics in Stanford University, was born in 1905 in Zurich, Switzerland, where he obtained his training (1924–27) in theoretical physics at the Federal Institute of Technology. He was awarded his doctor's degree in Leipzig (1928), where Prof. W. Heisenberg was pursuing his fundamental studies on quantum mechanics, and the following years were spent in Holland and in Copenhagen with Prof. Niels Bohr. In 1933 Bloch became *Privatdozent* under Heisenberg and was awarded, in the same period, a Rockefeller Fellowship which led him to Prof. E. Fermi in Rome.

During these years Bloch published papers on quantum theory, the electrical and magnetic properties of crystals, and produced his basic contribution to ferromagnetism. Also into this period falls his work on the energy losses of fast charged particles, a paper the results of which are still of great use to nuclear physicists.

When the intellectual climate in Germany became intolerable, Bloch emigrated, in 1934, to Stanford University, California, where he became associate professor of mathematical physics. He continued his theoretical studies, mostly on problems about interaction between radiation and matter and on nuclear physics, but became also interested in experimental physics. In 1940, in collaboration with Alvarez, he was the first to determine the magnetic moment of the neutron. War research at Stanford University, at the Los Alamos Laboratory and at Harvard University occupied the years 1942–45. As soon as conditions permitted, Bloch returned to Stanford, taking up theoretical and experimental research in physics. Papers on neutron polarization by ferromagnetic media and studies of the behaviour of atoms in a time-varying magnetic field followed. In 1946 Bloch published his theory, and also, in collaboration with the late W. W. Hansen and M. Packard, the experimental method, which he called nuclear induction, of measuring nuclear magnetic moments with greatest precision. The method resembles that of Rabi, of Columbia University, in so far as transitions are induced by a radio-frequency field between the sub-levels of a nucleus placed in a magnetic field. The great advantage of Bloch's method lies in the fact that one can use bulk material and pick up the induction signal with a coil. The sharpness of the resonance has permitted the attainment of a very high accuracy of the measurement of nuclear magnetic moments, and the sensitivity of the method permits the study of nuclear species available in only small quantities, such as tritium. The nuclear induction method has spread to a great many laboratories, and its use for measuring magnetic fields in terms of the proton nuclear moment is now a standard technique. Many new and unexpected features have been discovered, such as the fine structure of the proton lines in organic compounds, an observation which may well open up a new tool for organic chemists.

Principal of University College of North Staffordshire: Sir John Lennard-Jones, K.B.E., F.R.S.

It has been announced that Sir John Lennard-Jones, Plummer professor of theoretical chemistry in the University of Cambridge, has been appointed principal of the University College of North Staffordshire, in succession to the late Lord Lindsay of Birker, formerly Master of Balliol College, Oxford, who was principal from the foundation of the College in 1950 until his death in March this year. Born in 1894, Sir John studied in the University of Manchester and Trinity College, Cambridge. During the First World War he was first a pilot in the Royal Flying Corps and then an experimental officer in the Armament Experimental Station at Orfordness. His first academic post was as a lecturer in mathematics in the University of Manchester, and then he moved to the University of Bristol as reader, and later professor, of mathematical physics. Since 1932 he has been Plummer professor of theoretical chemistry in Cambridge. During the Second World War he served in a scientific capacity in the Ministry of Supply, being for three years chief superintendent of armament research and later director-general of scientific research (defence). Since 1947 he has been chairman of the Scientific Advisory Council of the Ministry. He has been president of the Faraday Society, and is now a member of the Scientific Advisory Committee of the National Gallery. Sir John, who is distinguished for his work in various branches of theoretical physics and chemistry, particularly the electronic structure of molecules, was elected to the Royal Society in 1933 and was made K.B.E. in 1946. He thus takes to his new post in North Staffordshire a wide experience of universities, scientific research and administration.

The Imperial Institute: Sir Harry Lindsay, K.C.I.E., C.B.E.

Sir Harry Lindsay retires at the end of January 1953 from the Imperial Institute, where he has held the post of director with great distinction since he succeeded Sir William Furse in 1934. The major qualification for this post is a living and working knowledge of the British Commonwealth overseas. Prior to his appointment, Sir Harry had been a member of the Indian Civil Service, serving in India during 1905–22 and finally as Indian Trade Commissioner in London until 1934. Incidentally, his father, grandfather and great-grandfather had all served in India in various capacities, both civil and military. Recognizing that the scientific side of the Imperial Institute was in good hands, Sir Harry devoted his main attention to improving the exhibition galleries and publicizing by lectures the importance of the Commonwealth countries, both the Dominion and the Colonies. He himself has given many of these lectures, and his personal experience, gained by visits to South Africa during 1936–37 on the occasion of the Empire Exhibition and on a lecture tour of Canada in 1938, made them particularly valuable. The development of the Imperial Institute Galleries has always been handicapped by lack of funds; but Sir Harry has managed to obtain much support from many of the Dominions and Colonies and also from industrial firms. As a result the galleries have been enriched by a valuable series of dioramas studied with pleasure and profit by the parties from schools which regularly visit them. During recent years, Sir Harry has maintained an active interest in the work of societies which have strong Commonwealth and educational ties. He was chairman of the Council of the Royal Society of Arts during 1947–49 and edited the "British Commonwealth Objectives" for the Society. He was president of the Royal Geographical Society during 1948–51, of the Geographical Association in 1949 and of Aslib in 1940, and for many years served on the Councils of the Royal Empire and Royal India, Pakistan and Ceylon Societies.

Mr. Kenneth Bradley, C.M.G.

Mr. Kenneth Bradley, who succeeds Sir Harry Lindsay on February 1, has had wide and varied experience in the Colonial Empire. He served in Northern Rhodesia as an administrative officer during 1926–39 and then as information officer until 1942. He laid the foundations of the present department, including the inauguration and development of a broadcasting service to the African population. In 1942 he went as Colonial Secretary and Financial Secretary to the Falkland Islands and, while there, took part in the establishment of bases for the Falkland Islands Dependencies Survey in the Antarctic. He received the C.M.G. in 1946 and early in that year was promoted to the post of Under-Secretary in the Gold Coast. He served there, acting as Colonial Secretary for most of the time, until 1948. In 1947 he was chairman of the Gold Coast Committee which recommended the establishment of the present Gold Coast University College. In the following year he retired from the Colonial Service in order to become the first editor of *Corona*, the professional journal of the Colonial Service. Mr. Bradley has, since he came to London, particularly interested himself in the task of spreading knowledge about the Commonwealth and has given many broadcasts and lectures and contributed widely to periodicals in Britain and throughout the Commonwealth. He is a recognized authority on African affairs. He has published several books on African subjects, of which the two best known are "The Diary of a District Officer" (Harrap, 1942; Nelsons, 1948) and "The Colonial Service as a Career" (H.M.S.O., 1950), and has in the press a history of the Roan Antelope and Mufulira copper mines and of the early development of Northern Rhodesia as a whole under the title "Copper Venture".

The Oxford Synchrotron

THE Oxford 140-MeV. synchrotron has recently been undergoing preliminary trials at 60 MeV. This machine was built with funds supplied by the Department of Scientific and Industrial Research. During the past year much trouble has been encountered owing to the charging-up of the orbit tube wall, but these difficulties are now being overcome. The X-ray yield so far obtained is moderate, a thin copper target irradiated to saturation at a metre from the target showing a copper-62 activity of about 10,000 counts per min. per gm.

Science in the University of Glasgow

FOR the present session there have been 225 new admissions to the Science Departments of the University of Glasgow, compared with 232 a year ago. There are about 179 research students. In all sections of the University the total number of matriculated students is now about 5,820. A new feature of the teaching of bacteriology in the University (under Prof. J. W. Howie as its Gardiner professor) is that it now ranks as a science subject for degree courses. It may be taken either as a single or double qualifying course for the ordinary degree, or as a principal subject of an honours curriculum, which includes courses in botany, zoology, chemistry and biochemistry. There is also a combined honours curriculum in bacteriology and biochemistry.

The following appointments have recently been made in the University: Dr. F. E. Moon has been appointed senior lecturer in agricultural chemistry; Imperial Chemical Industries Fellowships have been awarded to Drs. M. F. Grundon and H. J. E. Loewenthal (for work in the Chemistry Department on curare and in the polycyclic field, respectively) and to F. C. Flack (gamma-ray spectroscopy in connexion with the high-tension set in the Natural Philosophy Department).

Synthesis of Vitamin B_{12} by *Rhizobium meliloti*

IT has been shown by M. O. Burton and A. G. Lockhead (*Canad. J. Bot.*, 30, 5, 521; 1952) that, of seventy strains of six species of *Rhizobium*, *R. meliloti* is sharply distinguished from the others by its ability to synthesize significantly larger quantities of vitamin B_{12}, one strain producing 1,000 mμ gm. per ml. of liquid culture medium. No correlation was observed between the vitamin-synthesizing capacity of individual strains and their effectiveness in nitrogen fixation.

Bristol Museum

THE annual report for 1951 of the City Museum, Bristol, is a good example of how provincial institutions accepted the challenge presented to them by the Festival of Britain. In Bristol it was decided to stage an exhibition portraying to some extent the topography and natural history of the city in 1851. One part of the large gallery was arranged realistically with lay figures and furniture to simulate the essential features of a drawing room. In addition, material and lay figures showed a hatter's and a sailmaker's workshop, while side panels depicted aspects of the railways, shipping, natural history and geology of the Bristol area in 1851. The report also describes new developments at the Museum during 1951, chief of which was the opening of a room specially for children making use of the Museum's service to schools. In addition, seventeen temporary exhibits were arranged as well as a series of winter lectures and conducted summer walks.

Proceedings of the Glasgow Mathematical Association

DURING the past fifty years the numbers of those engaged in research in pure mathematics has increased many times; but there has been no corresponding increase in the number of British journals available for the publication of their work. We therefore heartily welcome the appearance of a new journal, entitled *Proceedings of the Glasgow Mathematical Association*, but actually containing papers not only from Glasgow but also from England, Canada and South Africa. Manuscripts from all parts of the world are invited, primarily, but not exclusively, on pure mathematics, and should be sent to the Editor, Glasgow Mathematical Association, Department of Mathematics, University, Glasgow, W.2. The *Proceedings* will be published each January and July, the first part having appeared in January 1952. Four parts will make up a volume of about two hundred pages. The prepaid subscription for each volume is £2 (or 6 dollars) post free, and single parts may be obtained for 10*s.* 6*d.*, from the publishers (Edinburgh and London: Oliver and Boyd, Ltd.) or from any bookseller.

Plant Breeding Institute, Cambridge

THE Plant Breeding Institute at Cambridge, for many years part of the School of Agriculture, University of Cambridge, which was responsible for its administration with the aid of grants from the Ministry of Agriculture and Fisheries, has now been constituted as an independent research institute. It will continue to be financed by grant-aid from the Ministry and to come under the scientific supervision of the Agricultural Research Council. The Institute now takes the form of a company limited by guarantee, and without share capital. The membership of the governing body is as follows: Sir Frank Engledow (chairman); Prof. G. E. Briggs; Prof. W. Brown; Mr. E. Cave; Prof. S. C. Harland; Prof. H. Ian Moore; Prof. J. W. Munro; Prof. T. G. B. Osborn; Mr. R. W. Ward.

Earthquake near Kamchatka

On November 4 at 16h. 58m. 20s. G.M.T., an earthquake occurred with epicentre, according to calculations made at the U.S. Coast and Geodetic Survey in Washington, at lat. 52¼° N., long. 159° E., near the east coast of Kamchatka. It was recorded strongly at seismological observatories throughout the world and had a magnitude of 8¼ on the Gutenberg–Richter logarithmic scale. This is a smaller magnitude than that of the great Sikang–Assam earthquake of August 15, 1950; but had the Kamchatka earthquake happened on land it would undoubtedly have occasioned great damage. Faulting probably took place in the sea bed near the epicentre, since a great tsunami or seismic sea wave resulted, and spread throughout the Pacific Ocean. It arrived at the coast of northern Japan about 20h. G.M.T. on November 4. The Hawaiian warning system was used, and the coastlands of several islands, including the Oahu coast, were evacuated in anticipation of the wave. When the wave arrived at Hawaii itself, it is reported to have been several feet high, and would have caused much damage had not precautions been taken. Waves from one to three feet high arrived at the Whangarei beaches in the north of New Zealand about 7 p.m. local time on November 5. When these waves arrived at Wellington, they were 6–8 in. high. No news has yet been received from the nearest town to the epicentre—Petropavlovsk on the Kamchatka Peninsula—nor from the International Seismological Association central station at Strasbourg. Immediately following the main shock, there were more than a hundred aftershocks. Further news is awaited.

Provisional readings, all in G.M.T., of seismograms at Pasadena were: *eP*, 17h. 08m. 23s.; *iP*, 17h. 08m. 37s.; *e*(*PP*), 17h. 11m. 0s.; *eS*, 17h. 16m. 39s.; *iS*, 17h. 16m. 48s.; *i*(*ScS*), 17h. 18m. 11s.; *eG*, 17h. 23·2m.; *iG*2, 19h. 22m.; max. *H*, 2,000 ± μ; and at Stuttgart: *iP*, 17h. 10m. 12·0s. compression; *i*, 17h. 10m. 14·6s. compression; *i* !, 17h. 10m. 21·0s. compression; *i* ! (*PcP*), 17h. 10m. 24·0s. dilatation; *iPP*, 17h. 13m. 20s.; *iS*, 17h. 20m. 10s.; *eG*, 17h. 31m. (*T* = 80 sec. !); *MQ*, 17h. 40m.; *MR*, 17h. 41–42m. (*Z* = 5,400 μ); *MR*, 17h. 50m.

The Night Sky in December

Full moon occurs on Dec. 1d. 12h. 41m., U.T., and new moon on Dec. 17d. 02h. 02m. The following conjunctions with the moon take place: Dec. 12d. 20h., Saturn 8° N.; Dec. 15d. 14h., Mercury 7° N.; Dec. 20d. 08h., Venus 2° S.; Dec. 21d. 02h., Mars 2° S.; Dec. 26d. 20h., Jupiter 7° S. Mercury is too close to the sun at the beginning of December for favourable observation, but at the middle and end of the month its times of rising are 6h. 05m. and 6h. 50m., respectively, and it can be seen for a short time before sunrise; owing to its large southern declination, it will not rise far above the horizon. Venus is an evening star, setting at 18h. 25m., 19h. 05m. and 19h. 50m. on December 1, 15 and 31, respectively. The visible portion of the illuminated disk varies from 0·75 to 0·65, and the stellar magnitude averages − 3·7. Mars, an evening star, sets at about 20h. 20m. throughout the month, stellar magnitude about 1·1. It is easily recognized during the middle of December close to γ and δ Capricorni. Jupiter is visible throughout the night, setting in the morning hours at 5h. 15m., 4h. 15m. and 3h. 10m. on December 1, 15 and 31 respectively, stellar magnitude about − 2·3. Saturn, a morning star, rises at 3h. 25m., 2h. 40m. and 1h. 40m. at the beginning, middle and end of the month, respectively, stellar magnitude 0·9, and is visible for some hours before sunrise in the constellation of Virgo. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Dec. 4d. 1h. 55m., 37 Gemi. (*R*); Dec. 6d. 5h. 11·7m., δ Canc. (*D*); Dec. 6d. 6h. 15·9m., δ Canc. (*R*); Dec. 28d. 1h. 24·3m., 16 Taur. (*D*); Dec. 28d. 1h. 31·4m., *q* Taur. (*D*); Dec. 28d. 1h. 50·7m., 20 Taur. (*D*); Dec. 28d. 1h. 53·7m., 21 Taur. (*D*). *R* and *D* refer to reappearance and disappearance, respectively. Winter solstice takes place on Dec. 21d. 22h. Observation of the Geminid meteors during the first week in December will be difficult owing to moonlight.

Announcements

The conference this year of the Universities of Great Britain and Northern Ireland, convened by the Committee of Vice-Chancellors and Principals, will be held in the Senate House of the University of London during December 12–13. There will be three sessions on the following subjects: halls of residence and student amenities; success and failure at the university; and vacation employment. The Conference is only open to delegations appointed by the universities and to specially invited guests. Further details can be obtained from the secretary of the Committee, J. F. Foster, at 5 Gordon Square, London, W.C.1.

On the occasion of the twenty-second annual general meeting of the Printing, Packaging and Allied Trades Research Association, an exhibition of the Association's work will be held at the Connaught Rooms, Great Queen Street, London, W.C.2, on December 4. The displays will illustrate the work carried out in the Association's laboratories on the chemistry and physics of printing inks, papers, the testing of packages and containers, bookbinding, and the protection of packages against insect attack. New apparatus and new wash-up solvents will be shown, and the manner in which the Association endeavours to place its findings before its members will be illustrated. Further details can be obtained from the Association at Patra House, Randalls Road, Leatherhead, Surrey.

The National Science Foundation and the University of Rochester are sponsoring a conference on high-energy nuclear physics to be held in Rochester, N.Y., during December 18–20. The conference will be financed by a 2,000-dollar grant from the Foundation and contributions from several industrial firms in Rochester. The conference will bring together about seventy nuclear physicists from the United States, Canada and Mexico to discuss recent research findings on high-energy particles and to plan future studies in this field. Further information can be obtained from the National Science Foundation, 2144 California Street, N.W., Washington 25, D.C., or from the Department of Physics, University, Rochester, N.Y.

In the April and May issues of *L'Astronomie* there are two accounts of the eclipse of the sun at Khartoum on February 25, with a number of photographs taken by J. Leclerc and E. Geneslay. The first account is by several authors, and the second by L. D'Azambuja, of the Paris-Meudon Observatory. These detailed descriptions will prove very helpful to everyone interested in solar eclipses.

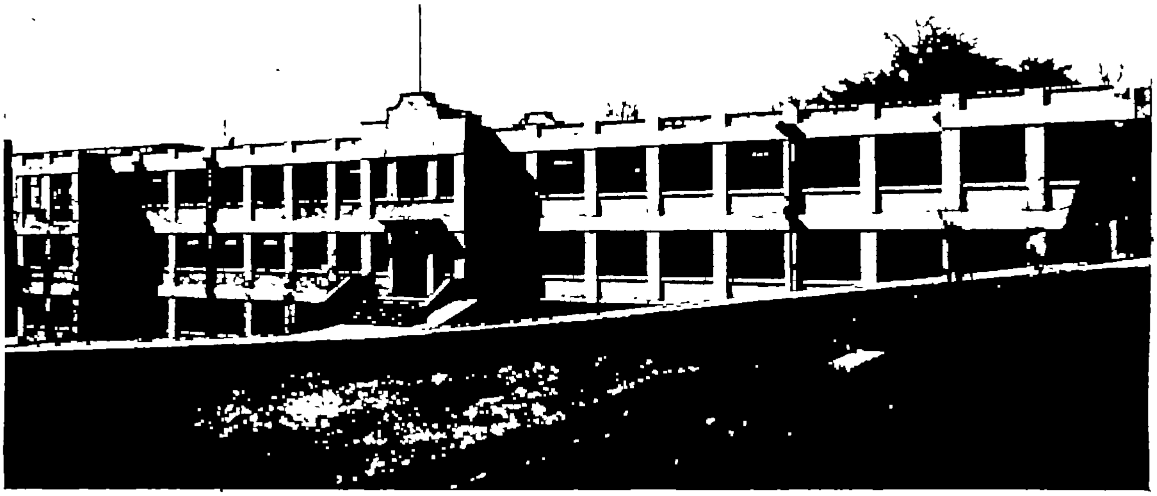
WOOL INDUSTRIES RESEARCH ASSOCIATION

EXTENSION TO LABORATORIES

POST-WAR extensions of the laboratories at Torridon, Leeds, of the Wool Industries Research Association were opened on October 17 by Viscount Swinton, Chancellor of the Duchy of Lancaster and Minister of Materials. The nucleus of the Research Association was formed in 1915 when a 'West Riding Research Committee' of interested industrialists, under the guidance of the late Sir Michael Sadler, vice-chancellor of the University of Leeds, initiated co-operative research which was financed by the local industry. This Committee was able to take full advantage of the Research Association scheme which was put forward by the Department of Scientific and Industrial Research in 1918. Indeed, the Wool Industries Research Association was the second to be formed under the ægis of the Department. The work of the Research Association was originally undertaken at the University of Leeds; but the need for separate laboratories soon became apparent, and in 1920 Torridon, a large residence standing in about four acres of ground, was purchased, and this provided reasonable accommodation for a limited number of laboratories and offices. In 1925 a shed was erected for woollen plant and later another was added for worsted plant, and in 1928 the adjoining estate of Longfield was purchased with a capital grant from the Empire Marketing Board. A new block was built for wet processing in 1939, and looms were installed in some of the original outbuildings.

In 1947 a progressive building plan was started. The wet-finishing block was extended to provide laboratory accommodation together with more extensive facilities for pilot-scale dyeing. This and three large new blocks have now been completed. The first contains pure and applied physics laboratories, including two large physical-testing laboratories where the atmosphere is controlled to 65 per cent relative humidity and 68° F. (20° C.), a drawing office and machine shop. As fibre properties are so sensitive to atmosphere changes, the whole of the block, other than the testing laboratories, is supplied with air maintained at 50 per cent relative humidity and 65° F., except when these conditions require the use of refrigeration. The second block to be finished houses woollen-carding and -spinning machinery, together with a raw-wool scouring plant in the basement. This block is also fitted with humidifying plant. The third block is for research on weaving and is equipped with a full range of preparatory machinery in addition to looms and with laboratory facilities. One room is humidified so that weaving can be done under a range of atmospheric conditions. The new buildings provide roughly sixty thousand square feet of floor area and with their equipment have cost about £250,000.

Research in the past has tended to be fundamental rather than applied, due largely to the big floor areas needed to house processing equipment. The new buildings were designed primarily to overcome this difficulty, and it should now be possible to undertake much more extensive research in fields that lead directly to increased industrial efficiency. As Lord Swinton said in his opening speech: "Research is the eyes of industry, and corporate research, industry combining for research, is the best of all; here in the Wool Industries Research Association you are, I think, a model because it is in very truth a partnership enterprise of a multitude of firms large and small. And those combined operations in the common interest have proved in this industry, as indeed in



New physics block at the Wool Industries Research Association others, to be no bar to individual initiative and competition." The new buildings are visible evidence of confidence in the success of corporate research because co-operation from all member firms will be essential if these facilities are to play their full part in promoting progress within the industry.

Wool is a most versatile fibre; there are in reality four wool industries—woollen, worsted, pressed felt and mechanical cloth, and the shoddy industry. The facilities now available provide for research ranging from the biology of wool growth to the finishing of fabrics, and although it is impossible to have even one example of every type of machine used in each of these separate industries, the methods and processes that are common to most of them can be fully investigated.

Perhaps the biggest expansion has been on the weaving side. Hitherto, facilities for work in this field have been negligible; but it is now possible to follow every process in preparing yarns for the loom and in weaving them on any of a representative range of looms. This is almost a virgin field for research so far as wool is concerned, and one that is likely to lead to fruitful results because much of the appearance of a finished wool fabric depends on the care with which the yarn is handled and wound between spinning and weaving.

Another aspect of the Association's work which has been increased and will benefit further from the extensions is operational research. The Association has undertaken this work in a small way for very many years, and as far back as 1947 it published to members a booklet on quality control in worsted spinning. The surveys now being made in mills, together with appropriate laboratory and pilot-plant work, provide information to members on the limits that can and should be worked to if optimum productivity and high-quality output are to be maintained with a proper economy in the use of consumable materials. The success of this work is shown by the increase in use of testing facilities in mills. It is worth noting that members installing these facilities often remark that only within recent years have test methods become available which are suitable for use in mills; and most of the examples they quote are the direct result of the Association's work.

The fundamental work of the Association, which has been so strikingly successful in the past, is continuing. Paper partition chromatography[1] was invented and developed in the Association's laboratories to determine the amino-acid composition of wool hydrolysates, work for which Dr. A. J. P. Martin and Dr. R. L. M. Synge have been awarded the Nobel Prize for 1952 (see *Nature*, November 15, p. 826). It continues to be used in the laboratories and has been improved in a number of respects, particularly with regard to the use of radioactive tracers to give a quantitative rather than a qualitative result[2]. Radioactive tracers are also in use to follow the diffusion of ions in keratin membranes, work which aims at elucidating the mechanism of dyeing. It has already yielded the result that hydrogen ions diffuse more slowly than those of bromine at low concentrations of hydrogen bromide[3]. This result is consistent with measured membrane potentials which previously seemed to be anomalous, and it can be quite simply explained on the theories of multimolecular adsorption and diffusion which have been developed for polymers at Torridon[4]. The earlier work of the Association on the importance of moisture absorption for clothing comfort and on the propagation of temperature and humidity changes through masses of textile materials[5] is now universally accepted and used throughout the world, as are the theory of water repellency of porous structures[6] and the theory of the effect of salts on ionic detergents[7].

A subject more recently studied, which has both practical and theoretical importance, is the dissipation of static electricity on fibres or polymer sheets. A solution has been found for the distribution of charge and the distribution of electric field in such systems, and the distribution of the field shows that conductivity in a liquid coating is much more effective in dissipating static charges than is conductivity of the fibre or sheet. Another subject of academic and practical interest is the friction between fibres or polymeric surfaces. Recent work has shown that, in contrast to the behaviour of metals, elastic rather than plastic deformation determines the frictional force; recognition of this difference between the two processes has explained many apparently anomalous features in the behaviour of polymeric materials during rubbing[8]. Thus, although the Association has planned for a large extension of work in the applied field, it has not lost sight of the need for fundamental research which so often inspires new ways of looking at practical problems, leading to their successful solution.

Finally, it might be mentioned that the Association's shrink-resisting process has been used by the Ministry of Supply since 1940 for Service socks and underwear. The Association has received £25,000 in royalties, and the increased life of the garments so treated has provided a saving to the Ministry of at least £5 million, which is several times the total expenditure of the Association since it was formed in 1918.

BRITISH STANDARD OF RADIOACTIVE IODINE (^{131}I)

In the autumn of 1948, at the request of the Medical Research Council, provisional British standards of certain therapeutically important radioactive isotopes were set up. The Atomic Energy Research Establishment[1] undertook the maintenance of standards of cobalt-60, sodium-24, and phosphorus-32; the maintenance of the iodine-131 standard was undertaken by the Radiotherapeutic Research Unit of the Medical Research Council at Hammersmith[2]. It was intended that these standards should serve for one year; their use has, in fact, continued until the present time.

Following an agreement between various interested bodies in 1950 that the National Physical Laboratory should be formally responsible for standards of this kind in Great Britain, workers from the Radiotherapeutic Research Unit, the Atomic Energy Research Establishment, the Royal Cancer Hospital and the National Physical Laboratory have met regularly to discuss standardization and to compare measurements on a number of isotopes. As a result of the improvements in standardizing techniques and of the more precise information now available about the iodine-131 disintegration scheme, it has been agreed that a revision of the 1948 standard for the substance is necessary.

In general, an isotope emitting β- and γ-rays may be standardized by counting methods which measure almost directly the number of nuclei disintegrating per second, that is, the number of curies present. An alternative method is the measurement of the γ-ray ionization in air under conditions which permit the result to be expressed in röntgens per hour at 1 cm. from a sample of radioactive material; which result can be converted to curies per gram of the sample by means of a factor (r./hr. at 1 cm. from 1 mC.) deduced from a knowledge of the disintegration scheme, of the γ-ray absorption coefficients in air, and of the energy required to produce an ion pair in air. The 1948 standard of iodine-131 was based on this latter procedure, which gave a conversion factor of 2·54 r./hr. at 1 cm. from 1 mC. of the isotope. Using subsequent information[3] about the disintegration scheme, and assuming that the energy required to produce an ion pair in air is 32·5 eV., the factor is deduced to be between 2·27 and 2·29 r./hr. These, and all other values of this factor quoted, exclude the small contribution due to X-rays arising from internal conversion and to bremsstrahlung which is of the order of 1 per cent of the total. (Experimentally, virtually complete elimination of the X-rays and bremsstrahlung can be achieved by absorption in 0·5 gm./cm.^{2} of copper.)

Recently, samples of iodine-131 have been distributed among the above-mentioned laboratories for measurements by counter methods, which include the defined solid-angle method using end-window β-counters, the 4π solid-angle Geiger–Müller counter, the 4π liquid scintillation counter and the β–γ coincidence method. The results by different laboratories, different counter techniques and different equipment varied by ± 5 per cent. The samples were also measured by three of the laboratories using the γ-ray ionization method. For this purpose, graphite chambers were used which were calibrated with γ-rays from standard radium sources, for which it was assumed that the dosage-rate at 1 cm. from 1 mgm. radium screened by 0·5 mm. platinum was 8·3 r./hr. The results obtained by the three laboratories varied over a range of ± 2·5 per cent. The measurement by the ionization method and by the counter methods were consistent with a value 2·25 r./hr. at 1 cm. from 1 mC. of iodine-131. Accordingly, it is now proposed that a figure of 2·25 r./hr. for the dosage-rate at 1 cm. from 1 mC. of iodine-131 (excluding the contribution due to X-rays and bremsstrahlung) should be adopted as the new standard. This differs from the previous standard in that a quantity of iodine-131 hitherto estimated as 1 mC. will now be 1·13 mC. The maintenance of the standard will be undertaken by the National Physical Laboratory; measurements will be made in terms of γ-ray ionization in graphite chambers, calibrated against a standard radium source (and using the conversion factor of 8·3 r./hr. already quoted), because of the greater convenience of this type of measurement compared with the direct counting methods. It is believed that values based on the new standard will not differ by more than ± 5 per cent from the true values.

A more detailed account is being prepared of the intercomparisons on which this new figure is based.

The mean energy emitted by iodine-131 in the form of β-rays and internal conversion electrons has been re-determined by the Radiotherapeutic Research Unit, using the lined-chamber method[1]. The value based on the new standard is 0·197 MeV. Taking into account all sources of error, this value is regarded as correct within 5 per cent.

FOLLOWING the review described above of the British standard of activity for the radioisotope iodine-131, the new standard will be used for dispensing this substance supplied by the Atomic Energy Research Establishment, Harwell, as from January 1, 1953. The provisional Medical Research Council standard, set up by Gray, which has been used for the assay of all consignments supplied by the Establishment from the beginning of 1949 until the present time, will be used for supplies dispensed up to midnight on December 31, 1952.

It should be noted that, whereas 1 mC. of iodine-131 measured by the provisional standard (1949) emits gamma-radiation at the rate of 2·54 r./hr. at 1 cm., 1 mC. of iodine-131 by the new standard gives 2·25 r./hr. at 1 cm. A factor of 1·13 therefore exists between the two standards, and the new standard millicurie will contain less activity than the old one.

No official intercomparison of standards for iodine-131 has yet been made between Great Britain and other countries. However, a series of unofficial measurements, relating standards from Chalk River, Canada, National Bureau of Standards, U.S.A., and Oak Ridge, U.S.A., indicate that the new British standard is in agreement with these, at least within experimental error.

STRUCTURAL FEATURES OF ANTITUMORIGENIC CORTICOIDS

By DRS ELVIRA MARDONES, R. IGLESIAS, F. FUENZALIDA, S. BRUZZONE and PROF. A. LIPSCHUTZ

Department of Experimental Medicine, National Health Service of Chile, Santiago

THE antifibromatogenic action of steroids is not related to any other known physiological action of the latter; it is an independent faculty[1,2]. Thus it seems likely that 'screening' of antitumorigenic steroids may be based, tentatively, on the assumption that the antitumorigenic potency is concomitant with certain structural features of these compounds.

Progress has recently been achieved on these lines in our work on the antifibromatogenic potency of various corticoids in castrated female guinea pigs receiving, during a period of three months, œstradiol as absorbed from a subcutaneously implanted tablet.

Control experiments with œstradiol alone. Of twenty-three animals with an absorption of 16–70 μgm. of œstradiol a day, nineteen had abdominal fibroids (fibrous tumoral effect = 3·9). (This control series is not identical with that of our earlier paper[1]. Any series in which the antifibromatogenic potency of steroids is tested is always accompanied by a new control series.)

Deoxycorticosterone (acet.; m.p. 159). Deoxycorticosterone has long been known as one of the most potent antifibromatogenic steroids, being inferior only to progesterone[3,4]. In a new series of experiments, prevention of abdominal fibroids was again obtained in all the eight animals in which 135–200 μgm. of deoxycorticosterone acetate per day was absorbed from one tablet (2·9 ± 0·1 μgm. per 1 sq. mm.) subcutaneously implanted. Only fibrous strands and some tiny nodules on the spleen were present (fib. tum. effect = 1·4). In a group of four animals with an absorption of 97–118 μgm. of deoxycorticosterone acetate per day from half a tablet, the average fibrous effect was still considerably diminished (= 2·5).

17-*Hydroxy-deoxycorticosterone* (Reichstein's compound *S* acetate; m.p. 233)[5]. This substance differs from deoxycorticosterone solely by $\mathrm{OH}--\mathrm{C}_{17}$. In a group of ten animals, absorption from one to three tablets was as much as 150–750 μgm. per day (2·9 ± 0·14 μgm. per 1 sq. mm.). All animals had abdominal fibroids (fib. tum. effect = 5·8).

One may infer from these results that the antifibromatogenic potency of deoxycorticosterone is considerably diminished by the substitution $\mathrm{OH}--\mathrm{C}_{17}$.

Dehydrocorticosterone (Kendall's compound *A*, acet.; m.p. 176°). This differs from deoxycorticosterone solely by $\mathrm{O}=\mathrm{C}_{11}$. In earlier experiments of shorter duration (two months only), it was found to be antifibromatogenic, though probably less than deoxycorticosterone[6]. In a new series of nineteen animals, this was corroborated, though the difference between deoxycorticosterone and compound *A* was found to be more considerable than in former experiments. Fibromatogenesis was greatly diminished (fib. tum. effect = 1·7) by about 356–417 μgm. of *A* acetate per day absorbed from half a tablet (7·2 ± 0·4 μgm. per 1 sq. mm.; this rapid absorption makes it necessary to implant a new tablet six weeks later); but there were fibroids with a dose of 90–110 μgm. of *A* acetate per day (fib. tum. effect = 4·9; 1–3 tablets containing but 40 per cent of *A* acetate and 60 per cent of cholesterol, permitting non-selective absorption[7,8]; figures not exact on account of the breaking up of the tablets).

The above results show that the antifibromatogenic potency decreases due to $\mathrm{O}=\mathrm{C}_{11}$, though in a much less pronounced degree than with $\mathrm{OH}--\mathrm{C}_{17}$. Cortisone is of considerable interest here, because it differs from deoxycorticosterone by both these substitutions.

Cortisone, or 17-hydroxy-dehydrocorticosterone (*E* acetate; m.p. 237°). In former experiments, abdominal fibroids were not prevented with 138 μgm. of *E* acetate per day absorbed from subcutaneously implanted tablets[9,10]. In a new group of three animals, there was again no prevention with 125–225 μgm. of *E* acetate per day (fib. tum. effect = 3·9; 6–8 tablets containing 40 per cent of cortisone and 60 per cent of cholesterol; absorption figures not exact). In a group of ten animals, as much as 457–1,050 μgm. per day were absorbed from 1–2 tablets (6·5 ± 0·14 μgm. per 1 sq. mm.; a new implantation was made six weeks later). Some prevention took place (fib. tum. effect = 2·3); but there were fibroids even with as much as 1,000 μgm. per day (2 tablets).

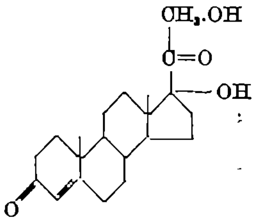
The difference between the antifibromatogenic potency of cortisone and deoxycorticosterone is very striking. But cortisone is also much less active than compound *A*. These findings are in full agreement with the statement that antifibromatogenic potency is diminished by $\mathrm{OH}--\mathrm{C}_{17}$. However, contrary to expectation, cortisone was seemingly somewhat more potent than compound *S*, with which it shares $\mathrm{OH}--\mathrm{C}_{17}$. That is to say, $\mathrm{O}=\mathrm{C}_{11}$, which by itself certainly diminishes the antifibromatogenic potency (*A* is less potent than deoxycorticosterone), appeared to counteract, or to reduce, the negative influence of $\mathrm{OH}--\mathrm{C}_{17}$ when simultaneously present with the latter. In view of very considerable variations as to the fibrous tumoral effect in a group of animals, it would seem wise not to attribute too much importance to the difference between compound *S* and cortisone. However, the unexpected phenomenon of reduced negative effect was shown in an even more striking way when compound *S* (17-hydroxy-deoxycorticosterone) was compared to compound *F* (17-hydroxycorticosterone).

17-*Hydroxy-corticosterone* (compound *F*, acetate; m.p. 218°). In two animals, 160–235 μgm. of *F* acetate per day were absorbed from one tablet (a new implantation six weeks later); in three animals 467–518 μgm. per day were absorbed from two tablets (2·6 ± 0·4 μgm. per 1 sq. mm.). There were no fibroids, only fibrous strands and small nodules being present (fib. tum. effect = 1·2). On the contrary, in five animals with 67–95 μgm. per day absorbed from ten tablets containing 40 per cent of *F* acetate and 60 per cent cholesterol, there was no prevention of fibroids (fib. tum. effect = 3·6).

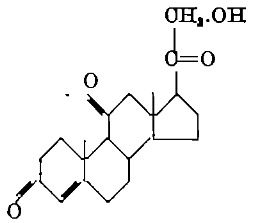
It would thus seem that, thanks to $\mathrm{OH}--\mathrm{C}_{11}$, compound *F* diverges as to antifibromatogenic potency from compound *S* and approaches deoxycorticosterone.

Suppression of the negative influence of a substitution by another one can be paralleled by older observations of ours. Whereas progesterone is the most potent antifibromatogen, pregnanedione and allo-pregnanedione, in which Δ^4 is lacking, are not antifibromatogenic[7]. On the other hand, dihydrotestosterone and methyl-dihydrotestosterone are as potent as testosterone and methyl-testosterone, or are more potent than these[11,12]. One may speculate that the interference of Δ^4 is no longer necessary when the side-chain of two carbons in C_{17} is eliminated or reduced to CH_3. (The OH in C_{17} in these antifibromatogenic androgens is in the beta position; on the contrary, the isomer of testosterone with $\mathrm{OH}--\mathrm{C}_{17}$ (formerly called cistestosterone) is not antifibromatogenic[10]. This is in full agreement with the above findings with compound *S*.)

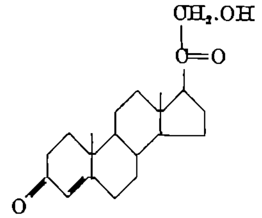
Our finding of a difference in antifibromatogenic potency between compounds *E* and *F* can be compared also to the statement that the latter is thirty times more active than compound *E* in inhibiting the growth of the chicken embryo and a hundred times more active than compound *E* in inhibiting the growth of the newly hatched chick[13]. The fact that such considerable functional differences exist



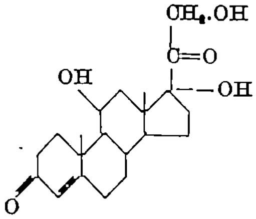
(S)



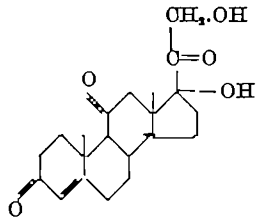
(A)



Deoxycorticosterone



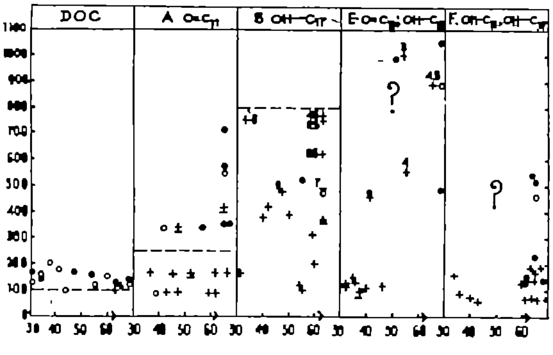
(F)



(E)

between these compounds is of great interest by tself; the recent suggestion that the steroidal output of the adrenal cortex consists predominantly of compounds *F* and *B* (corticosterone) also should be mentioned here[14]. We are fully aware of variations of the fibrous tumoral effect one meets with in similar experiments even when prolonged for a period of three months, and which may lead to contradictory results. Comparative work with compounds *S* and *F* is continuing in this Department.

The accompanying diagram summarizes the experiments discussed above and also additional experiments with Reichstein's compound *S* and Kendall's compound *F*. Whereas the negative influence of OH -- C_{17} (compound *S*) has been fully confirmed, the 'protective' action of OH - C_{11} against OH -- C_{17} compound *F*) remains so far doubtful.



+, Animals with tumours; O, animals without tumours, only fibrous strands being present; ±, animals with not more than one tumoral note grade 1. Abscissa: absorption of œstradiol per day (μgm.); ordinates: absorption of 3-keto steroids per day (μgm.)

Thanks are due for a generous supply of œstradiol, deoxycorticosterone and compound *S* to Dr. A. White, director of research, and Dr. I. V. Sollins, Chemical Specialties Co., New York, and Syntex, S.A., Mexico; of cortisone to Drs. C. Miescher and A. Wettstein, of Ciba, Basle; and of cortisone, compounds *A* and *F*, to Drs. R. T. Major and A. Gibson, of Merck and Co., Rahway, N.J. Thanks are also due to the Rockefeller Foundation, the Jane Coffin Childs Memorial Fund for Medical Research, and the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation, for grants afforded in previous phases of our work. The technical help of Mrs. R. A. de Ulloa while working for her M.D. thesis is also acknowledged. [April 16.

PASSAGE OF THE SPERM AND THE PENETRATION OF THE EGG IN MAMMALS

By C. R. AUSTIN and A. W. H. BRADEN
Division of Animal Health and Production, C.S.I.R.O., McMaster Animal Health Laboratory, Parramatta Road, Glebe, N.S.W.

THE wealth of detail in a recent comprehensive review of this subject[1] bears witness to the large volume of information which is available on fertilization and associated phenomena in mammals. Although much of the information is rather disconnected in form, some underlying principles are becoming more clearly defined. In particular, it seems possible now to derive a logical concept of those processes which lead up to the fertilization of the mammalian egg, and it is with this object in mind that the present communication has been prepared. The specific aspects to be considered include the time relations of œstrus, ovulation and coitus, the distribution and rate of travel of sperms in the female genital tract, and the mechanism of sperm penetration into the egg.

Number of Sperms in the Female Tract

The number of sperms in a single ejaculate varies with the species of mammal but generally is of the order of 100 million–1,000 million. The semen may be ejaculated into the uterus, as in the rat, mare and sow, or into the vagina, as in the rabbit, ewe, cow and bitch.

In striking contrast, the number found in the Fallopian tube, and particularly the ampulla, which is the usual site of fertilization, is relatively very small. Mean figures for sperm counts, mostly at the time of ovulation, are available for several species: from 5–43 in the ampulla of the rat[2-4]; 2,000 and 3,000 in the whole tube of the rabbit[4,5]; 5,300 in the whole tube of the ewe[3]; and in the ferret about 200 in the ovarian capsule, which is the probable site of fertilization in this animal[7].

The wide difference which exists between the number of sperms present in the uterus or vagina on one hand and the Fallopian tube on the other, can be imputed to the properties of the female tract and particularly to the utero-tubal junction. The influence of the utero-tubal junction on the distribution of sperms in the genital tract of the rat is clearly shown by the results obtained by Blandau and Odor[4]. The mean number of sperms found in both uteri soon after mating was 58 million, whereas the mean number in the tubes soon after ovulation was 882.

Similarly in the rabbit, Braden (unpublished data) has found that the ratios of the numbers of sperms in the vagina, uteri and tubes of twelve mated rabbits about the time of ovulation was 350 : 450 : 1.

A remarkable degree of selectivity has been demonstrated for the utero-tubal junction of the rat[8]. When rat sperms were mixed with those of the bull, mouse or guinea pig and placed in the uterus, passage into the Fallopian tube was almost completely restricted to the rat sperms.

Time Relations of Sperm Travel

The interval between coitus and the arrival of the first few sperms at the site of fertilization is difficult to establish with certainty, and authorities vary widely in their estimates. The indications are that in many species this interval is remarkably short: times in the neighbourhood of 15 min. or less have been reported for the mouse[8], rat[10], bitch[11], ewe[12] and cow[13]. The brevity of the interval suggests that, at least in these species, the passage of the sperm is effected mainly by the movements of the genital tract, and that the motility of the sperm is of secondary importance.

The interval between coitus and ovulation also varies with species. A few animals, such as the rabbit, ferret and cat, exhibit the phenomenon of copulatory ovulation; the shedding of the egg is controlled by a neuro-hormonal mechanism for which the stimulus is the act of coitus. In most species, however, ovulation occurs independently of mating, though the period of sexual receptivity begins some hours before ovulation. In either circumstance, and where full opportunity exists, there will normally be an interval between coitus and ovulation which may be as short as 10 hr. (rat and rabbit) or as long as 30 hr. (cow and ferret) or several days (mare). Owing to the rapidity of sperm travel, sperms may be present at the site of fertilization for the greater part of these periods before the eggs become available for penetration.

It may happen that, through mischance or experimental intervention, the opportunity for mating is lacking for the early part, or for most, of the period of receptivity. In these circumstances the females of many species will permit coitus shortly before or even a little after ovulation. It has been observed, however, in the rabbit[14], cow[15], ewe[16] and sow[17] that such delayed mating or late artificial insemination results in a reduced incidence of pregnancy and number o young. The effect becomes the more evident th longer the delay; but is noticeable well before th end of the fertile life of the egg.

Penetration of the Egg

The mammalian egg consists of a vitellus enclose by a thick transparent membrane, the zona pellucida In the ovary the mature egg is surrounded by a mas of follicle cells, in which two layers are distinguished an inner layer of densely packed, radially arrange cells, the corona radiata, and an outer layer o sparsely distributed cells, the cumulus oophorus. Th cells of the cumulus are embedded in a hyaluroni acid gel which also fills the spaces between the cell of the corona. For a period after ovulation the eg continues to be surrounded by a variable proportio of the follicle cell mass; the amount is large in th rodents and rabbit, moderate in the bitch and cat and small in the ewe, cow and mare.

To enter the egg, the sperm must traverse th cumulus, corona, zona, and the surface of the vitellus It appears to be well established now that the sperm penetrates the gel matrix of the first two layers wit the aid of the enzyme, hyaluronidase, which i carries[18-20]. The sperm is known to pass through th apparently intact cumulus in the mouse, rat an rabbit, so that actual denudation of the eggs is not necessary preliminary to penetration[4,9,21,22]. Denudation does occur, but not until later stages o fertilization[9]. Passage through the zona may also b effected by an enzyme, possibly associated with structure on the leading surface of the sperm head[23,24] A small slit in the zona of the rat marks the poin at which a sperm has entered[25]. The penetration o the vitelline surface, on the other hand, seems rathe to be a function of the vitellus which, observed *i vitro*, appears to absorb the sperm[25].

It has long been known that in most invertebrate and lower vertebrates only one sperm normally enter the vitellus and takes part in the process of fertilization. In these species, the entry of more than on sperm into the vitellus, 'polyspermy', has been foun to result in early degeneration of the egg. Polysperm is rare in the mammalian egg, though no detaile study of the incidence or ultimate results of this stat appears to have been made. In a recent investigatio on the cytology of fertilization[9], only four polyspermic rat eggs were seen among a large series. Th bar to polyspermy in mammals is thought to involv a change in the surface of the vitellus. It is certai that the zona offers no protection against polyspermy for supernumerary sperms are common in the thickness of the zona or in the perivitelline space. Hensen[2] reported the presence of about fifty supernumerar sperms in the rabbit egg, and numbers of the orde of 20–30 have been noted recently in a more detaile study[5]. In the rat, it has been found that 23 per cen of eggs contain from 1 to 5 supernumerary sperms[25] The smaller number seen in rat eggs is consisten with the smaller number of sperms in the Fallopia tubes of this species.

There is no unequivocal evidence of chemotaxi between egg and sperm in animals[27,28]. The chance of penetration may, however, be improved by othe mechanisms: the radially arranged coronal cell would tend to direct the movements of the approaching sperm towards the egg; the adherence of the sperm head to the surface of the zona, very eviden with the rabbit egg *in vitro*, would have a trap-lik action.

Capacitation of the Sperm

Evidence is accumulating that the sperm must emain within the female tract for a period before it s capable of penetrating the egg. If sperms are ntroduced shortly after ovulation into the periovarian ac of the rat, they are soon found about the eggs in he Fallopian tube, but are not seen within any eggs until four or five hours after their introduction[24]. Similarly, in rats which are not permitted to mate until after ovulation, sperms are found at the site of fertilization one hour after mating, but no penetrated eggs are observed until 2–2½ hours after mating[31].

Failure of penetration, within several hours following the introduction of sperms into the Fallopian tube, has also been reported for the rabbit[25,32].

The main obstacle to penetration appears to be the zona pellucida, and the indications are that the sperm must undergo some form of physiological change or capacitation before it is able to traverse this membrane. Capacitation normally requires residence within the female tract; but recent studies with rabbit eggs suggest that capacitation may occur *in vitro* if sperms are incubated in the presence of tubal secretions[33].

Conclusions

The present trend of research on the processes eading up to fertilization in mammals permits a fuller appreciation of the significance of two phenomena: the distribution of sperms in the female tract and the lapse of time between the onset of sexual receptivity and ovulation.

The weight of evidence now available indicates hat the number of sperms which gather at the site of fertilization may be regarded as no more than a compromise between two simple requirements. On one hand, the larger the number of sperms at the site of fertilization the better will be the chances for he meeting of egg and sperm. On the other hand, he danger of polyspermy, from which there is imperfect direct protection, will be reduced in the presence of small numbers of sperms. The problem eems to be resolved by the presence under normal onditions of a small excess of sperms above the minimum necessary to provide good chances for the penetration of all the eggs. The actual number of sperms involved will vary in different species, since the chances of meeting will be influenced by the volumetric capacity of the genital tract and especially the site of fertilization. This control of sperm number s held to be an important and overt function of the emale genital tract, and particularly of the uterotubal junction.

The passage of the sperm through the cumulus oophorus is made possible by an enzyme which it carries, and a similar mechanism may enable the sperm to pass through the zona pellucida. An nportant difference, however, exists between these wo processes; for, although the freshly ejaculated sperm is capable of traversing the cumulus, it pparently cannot penetrate the zona until it has ndergone some form of physiological change or capacitation.

Time is required for the passage of the sperm to he site of fertilization and for the accumulation there f adequate numbers to provide good chances for the meeting of sperm and egg. The lapse of time between the onset of sexual receptivity and ovulation appears in many species to be well in excess of these requirements. The interval, however, is not unduly long when it is considered that time is needed also for the capacitation of the sperm, which may take much longer than the transit of the sperm, and that some latitude is clearly advantageous as the opportunity for mating may not exist at the beginning of receptivity. It seems probable that the low fertility which has been observed in some species when mating or artificial insemination is performed about the time of ovulation may be imputed to a failure of completion of the capacitation process before the egg nears the end of its fertile life. SITE OF ACTION OF MUTAGENIC REAGENTS

Nitrogen Mustards

NITROGEN mustards are of interest for the treatment of some types of cancer. We have endeavoured to find the site of action in the cell of one of these compounds (ββ dichlorodiethyl methyl amine) by transfer of nuclei between treated and untreated amœbæ. We have used *Amœba discoides* and *A. proteus*. The figures quoted below are for *A. proteus*.

Amœbæ were given an exposure of fifteen minutes to various concentrations of nitrogen mustard. It is possible to treat either normal amœbæ or enucleated cytoplasm, but not isolated nuclei, with the drug. Transfers of nuclei may then be made between normal amœbæ and treated amœbæ (or cytoplasm). From examination of such transfers the following conclusions were derived.

(1) The L.D.50 for nuclei is 0·00015 per cent nitrogen mustard.

(2) The L.D.50 for cytoplasm is 0·0015 per cent nitrogen mustard.

(3) The cytoplasm is independently damaged, that is, by a direct action of the drug.

(4) The nuclei are probably damaged independently of the cytoplasm, that is, by a direct action of the drug.

(5) If the cytoplasm is lethally damaged, cell division never occurs.

(6) If the nuclei are lethally damaged, nuclear division usually occurs unless the nuclei are present in very badly damaged cytoplasm. Division of the nuclei is not necessarily followed by cytoplasmic division. If damaged nuclei are in normal cytoplasm, cytoplasmic division normally follows nuclear division; but if the cytoplasm is also damaged the probability of cytoplasmic division varies inversely as the amount of damage.

(7) Division of the amœbæ is delayed to an increasing degree with exposure to increasing concentrations of nitrogen mustard. The first division after treatment is little delayed unless lethal damage has occurred. The second division is much more sensitive than the first, and the delay increases more rapidly with increase in concentration.

(8) Other abnormalities observed included: unequal division; prolonged prophase with death of amœba before completing division; failure of nuclear reconstruction after mitosis; division into more than two cells (up to seven), some of which may be anucleate.

X-Rays

In view of the results recorded in the previous communication it was decided to study the site of action of X-rays by a similar technique. Most experiments were made with a 400-kVp. machine, providing a dose-rate of 3,000 r. per minute. Some results were obtained using a 10-kV. machine giving a dose-rate of 27,300 r. per minute. Using the technique of nuclear transfer, the following conclusions were reached with *Amœba proteus*.

(1) The L.D.50 for nuclei is 120,000 r.

(2) The L.D.50 for cytoplasm is 290,000 r.

(3) The cytoplasm is independently damaged, that is, by a direct action of the radiation.

(4) Cytoplasmic damage is of two types: reversible damage already maximal at less than 100,000 r.; and lethal damage becoming prominent above 280,000 r.

(5) The nuclei are probably damaged independently of the cytoplasm.

(6) If the cytoplasm is lethally damaged, cell division never occurs.

(7) If the nuclei are lethally damaged, nuclear division seldom occurs. If division of a lethally damaged nucleus does occur, it is normally followed by cytoplasmic division.

(8) Division of the cytoplasm is delayed and is normally preceded by nuclear division. The delay reaches a maximum at 120,000 r. This delay is prominent for the first division, and small for th second division.

The main differences observed between the actio of X-rays and of nitrogen mustard were:

(*a*) The nuclei are ten times more sensitive t nitrogen mustard than is cytoplasm, compared wit a ratio of 2·5 for X-rays.

(*b*) The slopes of the dosage-mortality curves bot for nuclei and for cytoplasm are steep for X-irradia tion and relatively flat for nitrogen mustard Consequently, a dose of X-rays which is just letha for all nuclei will not cause any lethal damage t cytoplasms, whereas an exposure to nitroge mustard which is just lethal to all nuclei will als cause lethal damage to some cytoplasms.

(*c*) Whereas with X-rays delay in division i prominent for the first division and small for th second, with nitrogen mustard the delay is small fo the first division and prominent for the second.

(*d*) Lethal damage to nuclei by X-rays usuall prevents nuclear division immediately, whereas wit nitrogen mustard nuclear division is usually possibl after lethal damage.

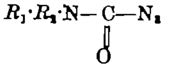
'AZIDINE' TRANSFORMATIONS

By F. L. SCOTT, A. KOCZARSKI and
Prof. J. REILLY

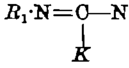
Department of Chemistry, University College, Cork

The carbamylazides, as a group, were classified by Bertho[1] as resistant to the Curtius rearrangement. However, other work[2] showed that while some members of this group (1, R_1 or R_2 = H, R_2 or R_1 = alkyl/aryl) failed to become rearranged, other (1, R_1 or R_2 = C_6H_5) did so.



$R_1{\cdot}R_2{\cdot}N{-}C(=O){-}N_3$

(1)

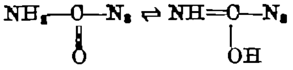


$R_1{\cdot}N{=}C(K){-}N_3$

(2)

Hurd[3] explained this anomaly by ascribing a hydroxyurea structure (2, K = OH) to the carbamylazides which resisted rearrangement. Hurd's formul contains the azidine system, a characteristic o which[4] is ready cyclization to substituted tetrazoles in the presence of bases. (By analogy with th nomenclature change of amide → amidine for th structural change $—CONH_2 \rightarrow —C(=NH)—NH_2$, i is suggested that, for the structural change $—CON_3 \rightarrow —C(=NH)N_3$, the nomenclature change should b from azide → azidine. This latter term does no appear to have been used previously in the literature. The expected cyclization product from carbamylazid (2, R_1 = H, K = OH) would be 5-hydroxytetrazol (3). Under a wide variety of reaction conditions, an with a large range of basic reagents, we have foun no trace of this cyclized material. Secondly, with ethereal diazomethane[5], two solids were isolated, analyses suggesting that one was a methylated carbamylazide (probably O-methylated since N-methylation with this reagent is rare), the other, of which only traces were found, a polymethylated urea. Because of the structural changes caused by bases, alkaline methylation of the carbamylazide affords different products.

From these observations, carbamylazide appears to display the following tautomerism:



$$NH_2\text{—}\underset{\underset{O}{\|}}{C}\text{—}N_3 \rightleftharpoons NH{=}\underset{\underset{OH}{|}}{C}\text{—}N_3$$

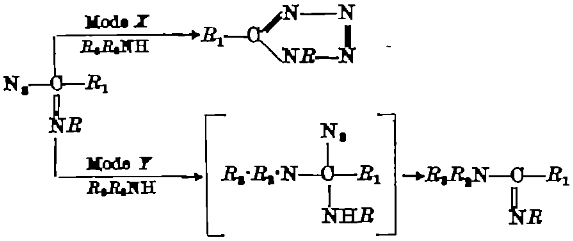
This equilibrium is displaced irrevocably to the right in the presence of diazomethane.

As the Curtius reaction is anionotropic[6], an interpretation, different from Hurd's, for the resistance of carbamylazide to such changes may be suggested. In general, with this type of transformation, the readiness of rearrangement depends upon the electrophilic powers of the migrating groups. Anionotropic migration must exceed the velocity of the other changes which may occur—and competitive reaction may be envisaged, migration-velocity (M_v) being necessarily greater than cyclization velocity (C_v) or replacement velocity (R_v)—for reactions of the Curtius type to take place.

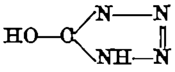
The electrophilic powers of the diphenylimino $(C_6H_5)_2N$—, phenylamino, C_6H_5NH— and the amino radicals are in reciprocal ratios to their basicities; thus, while the first readily undergoes anionotropic rearrangement (M_v being greater than C_v or R_v), the others, because of their greater basicities, have C_v/R_v greater than M_v and hence fail to undergo the intramolecular migration.

Replacement of the azide group alone is not sufficient proof of the absence of the azidine structure (*vide infra*). However, the observation that no cyclization occurs in the presence of basic reagents too weak to cause replacement was taken as an indication of the absence of azidine nature.

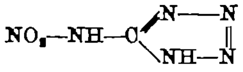
With the azidines the two main courses of reaction which may occur in place of the Curtius type are as follows:



Guanylazide[7] with hydrazine hydrate reacts exclusively by mode Y and with substituted hydrazines[8] by mode X, while nitroguanylazide[9,10] reacts preferentially by mode X in the presence of amines—due to the enhanced acidic powers of 5-nitroaminotetrazoles (4)—but in the presence of hydrazines by mode Y. Usually products derived from simultaneous reactions by both modes X and Y result. A third and rarer course of reaction may occur[11], namely, mode Z, $RC({=}K)N_3 \rightarrow RC({=}K)N<$ (followed by various modes of decomposition of this free radical, for example, attack of the solvent, to give $RC({=}K)N$—hydrocarbon); but only when the Curtius, or the alternatives X or Y, reactions do not take place.



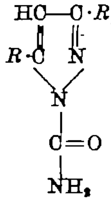
(3)



(4)

NH_2—CO·NH·NH·CO·NH_2

(5)



(6)

With carbamylazide, reaction in the presence of bases is exclusively that formulated in mode Y, and offers a new route for the preparation of ureas (and semicarbazides). From the results of Lieber *et al.*[12], the acid strength of 5-hydroxytetrazole, the possible cyclization product of carbamylazide by mode X, should at least be comparable to that of 5-aminotetrazole and hence should not offer any *a priori* obstacle to the base-produced cyclization. The nature of the azide, then, is apparently the sole determining factor in its stability towards the Curtius transformation.

With amines, reaction is rapid and results in high yields of the monosubstituted compounds. Towards diphenylamine, however, and towards amides and imides, the reagent is inert. With hydrazines, reaction is rapid to yield the monosubstituted semicarbazides; only with hydrazine itself does a disubstituted product, hydrazodicarbonamide (6), result. Towards 2,4-dinitrophenylhydrazine the reagent is inert. With amino-acids, under a wide variety of conditions, no hydantoins or hydantoic acids result, except in the case of isoleucine.

The ammonolysis of 1-carbamylpyrazoles (6) at present under investigation provides another route to these substituted ureas.

With thiocarbamylazide[13] another mode of reaction takes place, desulphurization occurring as a preliminary to reaction. The further steps, in this case, while not cyanamide formation, as earlier workers believed, are still under investigation. [May 17.

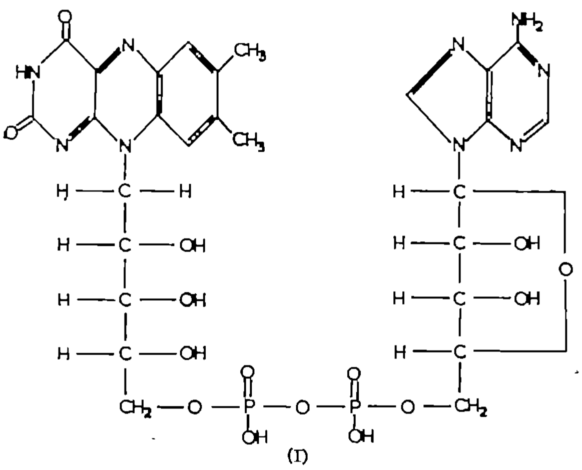
Total Synthesis of Flavin-adenine-dinucleotide

FLAVIN-ADENINE-DINUCLEOTIDE (FAD) is the coenzyme of a number of flavoprotein enzymes functioning as oxidation-reduction catalysts in biological systems. Isolated in 1938 by Warburg and Christian[1], it was assigned a probable structure (I) on the basis of available degradative evidence, although its preparation in a pure state has probably been rarely accomplished since its original isolation. Flavin-adenine-dinucleotide is structurally related to several other equally complex coenzymes (for example, coenzymes I and II, uridine-diphosphate-glucose and coenzyme *A*) in that all of them appear to be diesters of pyrophosphoric acid, in which one ester group embraces a pyrimidine or purine nucleoside residue, and indeed the members of the group are usually described loosely as nucleotide coenzymes. No chemical synthesis of any of these coenzymes has hitherto been achieved, although both flavin-adenine-dinucleotide and coenzyme-I have been prepared by enzymic reactions[2].

Over a period of years an extended series of investigations has been undertaken in this laboratory, having as its object the clarification of structural problems in the general field of nucleotide chemistry using the methods of synthetic organic chemistry. These researches have led to the structural elucidation and total synthesis of the ribonucleosides, and the development of a range of flexible methods for phosphorylation and polyphosphorylation of nucleosides[3]. Following the demonstration of the validity of our approach by the synthesis of adenosine triphosphate (ATP)[4], we have devoted increasing attention to the problem of synthesizing unsymmetrical diesters of pyrophosphoric acid of the nucleotide coenzyme type by unambiguous and generally applicable methods. As one of our initial objectives, flavin-adenine-dinucleotide was selected, since not only had riboflavin and adenosine been synthesized, but also we had devised convenient methods for the preparation of riboflavin - 5′ phosphate[5] and adenosine - 5′ phosphate[6], both of which could be regarded as possible intermediates.

Many attempts were made to apply methods involving disproportionation of polyphosphates and other mixed anhydrides to this problem (notably by Drs. H. S. Forrest and H. S. Mason[7]); but these failed, partly owing to the adverse physical properties of riboflavin and its derivatives, and partly owing to the tendency of the basic catalysts employed to disrupt any flavin-adenine-dinucleotide which might have formed. Arising from this work, however, came an understanding of the behaviour of mixed anhydrides of the oxy-acids of phosphorus, and this provided a novel method for preparing mixed diesters of phosphorous acid which could be applied to the nucleosides. Using it, we were able to synthesize 2′ : 3′-isopropylideneadenosine-5′ benzyl phosphite[8], and from it in turn 2′ : 3′-isopropylideneadenosine-5′ benzyl chlorophosphonate[9]. Condensation of this chlorophosphonate with the monosilver salt of riboflavin-5′ phosphate under carefully controlled conditions yielded the monobenzyl ester of the 2′ : 3′-isopropylidene derivative of (I). Debenzylation, followed by removal of the isopropylidene residue by treatment with acid under conditions which minimized fission of the pyrophosphate linkage, furnished P_1-riboflavin-5′ P_2-adenosine-5′ di-hydrogen pyrophosphate (I), identical with flavin-adenine-dinucleotide from natural sources in chromatographic behaviour (two solvent systems), chemical properties and ultra-violet absorption spectrum. When combined with the flavin-adenine-dinucleotide-free apoenzyme of D-amino-acid oxidase, the synthetic material gave a fully active reconstituted enzyme[10]; in the test solution used the value of 91 per cent was obtained for content of flavin-adenine-dinucleotide as expressed in terms of intensity of light absorption at 450 mμ[1]. We are indebted to Prof. D. Keilin and Dr. E. F. Hartree for carrying out these enzyme experiments.



(I)

This synthesis of flavin-adenine-dinucleotide not only establishes the correctness of structure (I), but it also opens the way to the synthesis of several other nucleotide coenzymes, and experiments in this direction are in progress. Full details of the synthesis here reported will be published elsewhere.

Evolution of Animal Fats

USING the theory of evolution as a general background, Hilditch and Lovern[1] have directed attention to the gradual simplification in the fatty-acid composition of animal fats as one proceeds from the lower forms of life to those that are more highly organized. In particular, they have noted the striking difference between the complexity of the fats of aquatic animals, which contain, in addition to C_{14}, C_{16} and C_{18} saturated acids, a wide range of unsaturated acids of the C_{14}, C_{16}, C_{18}, C_{20} and C_{22} series, as compared with the fats of the more highly evolved land mammals, which generally contain as major components only three acids, palmitic, stearic and oleic.

From consideration of the results[2] of the Fats Research Laboratory, New Zealand, together with those of other workers, however, it is suggested that the observed increasing simplicity of animal fats, as one proceeds from the lower to the more highly organized forms of animal life, is largely due to the fortuitous influence of the diet and only in part to the animals themselves. Thus, for example, aquatic mammals or birds deposit fats which are of the complex aquatic type, whereas land mammals or birds, which feed on fats of relatively simpler composition, deposit simpler types of fats[3]. On the other hand, it is now suggested that the major trend of evolutionary development on fats is discernible with respect to the fat metabolism of animals as follows:

(*a*) In the early stages of evolutionary development of fats in animals, the organism, as exemplified by fishes, is able to assimilate the dietary fat and so deposit it in its tissues more or less in the form present in the diet, subject, of course, to minor modifications induced by hydrogenation, dehydrogenation and in some instances to lengthening or shortening of the carbon chains. At this stage of development, the organism is apparently unable to make fat[4] (here termed 'synthetic' fat) from the non-fatty (protein and carbohydrate) constituents of the diet.

(*b*) In the next stage, as exemplified by amphibians, reptiles and most mammals, there is acquired, in addition to the ability to deposit the dietary fat mainly in its original form in the depot fat, an ability to make 'synthetic' fat. Such 'synthetic' fat is more or less of a uniformly simple composition and contains, as its main components, palmitic, stearic and oleic acids. The final composition of the depot fats of these animals will largely depend on the relative proportions of the dietary and of the 'synthetic' fats.

(*c*) In the final stage, the organism, as exemplified by certain ruminants, largely loses the power to deposit the fat from the diet[5], the constituents of which are broken down by the bacteria of the rumen before assimilation by the animal. The dietary fat no longer has any appreciable influence on the composition of the depot fat, which now consists almost entirely of 'synthetic' fat, with palmitic, stearic and oleic acids as the major constituents.

From the above conception of the factors which determine the fatty-acid composition of the depot fats of animals, it follows that the complexity of the fats of the less highly organized animals, such as fishes, is largely due to the fatty-acid composition of the diet, as, indeed, is indicated by the fact that fish, when fed unusual diets, will deposit in their depots fats which are different from the usual aquatic type. For example, grass-fed carp deposit in their fatty depots the diene and triene acids, characteristic of the grass lipids, but not characteristic of the fats of other aquatic species[6]. Eels, when fed fats of fatty-acid composition different from that originally present in their depots, have been shown to modify their depot fat to resemble more closely the dietary fat[6]. Further, it follows that if the dietary fat was similar in fatty-acid composition to that of 'synthetic' fat, all groups of animals would tend to lay down fats of somewhat similar fatty-acid composition; but if fed a dietary fat of different fatty-acid composition as, for example, linseed oil, then differences in fatty-acid composition of the depot fats would be observed as follows. Animals which had reached the first stage of development in regard to fat metabolism (*a*) would have fat in their depots of which the fatty-acid composition resembled that of linseed oil. Animals in the second stage of development (*b*) would lay down fats consisting of a mixture of 'synthetic' fat and linseed oil, the proportions of the latter in the depot fats depending on the proportions in the diet and on the rate of growth (cf. Callow[7]), whereas animals in the third stage of development (*c*) would show in their depots no appreciable evidence of linseed oil, but their fat would consist almost entirely of the 'synthetic' type.

From the work of Anderson[8], it is apparent that bacilli are able to synthesize lipids from non-fatty sources. The fatty material in this instance, however, is non-glyceridic in nature and, moreover, contains, for the most part, branched-chain fatty acids in contrast to the straight-chain even-numbered carbon-atom acids characteristic of the rest of animal and plant life.

Consideration of the nature of the bacillary lipids in relation to those already described above suggests that the evolution of fatty substances has commenced and ended with forms that are capable of making fats from non-fatty sources but incapable of depositing the dietary fat in their depots. The complexity of the fatty materials synthesized by bacilli from non-fatty sources, however, contrasts strikingly with the relative simplicity of the fats synthesized in the depots of ruminants. The evolution of fats thus appears to illustrate the loss and recovery of function, albeit in a somewhat changed form, during the development of the organism from less-specialized into more-specialized forms, and the discovery of branched-chain fatty acids in fats of ruminants[9] may be evidence of a vestigial characteristic carried through during development from bacteria to the more specialized forms of life.

DR. F. B. SHORLAND'S letter on this subject may serve to direct attention to the large number and variety of animal fats the component acids of which are now known with adequate quantitative accuracy. This number is nevertheless still small in comparison with the large number of species of which the fats await similar study.

Dr. Shorland's conclusions in regard to the progressive changes in the capacity of animals to produce comparatively simple 'synthetic' fats consisting mainly of combined palmitic, stearic and oleic acids as well as, or instead of, merely assimilating dietary fat are constructive and broadly accord with the general trend of the facts so far elicited. At the same time, as one would expect in so complex a field, many animal fats do not appear at first sight to fall smoothly into place in his classification. A few instances may be mentioned here which suggest that Shorland's outline is, as he would doubtless agree, in the nature of a preliminary statement which will require in due course further elaboration or modification.

(*a*) The variation of fatty-acid composition within the complex types of marine animal fats is probably as great as that which characterizes fats of his second and third classes (amphibians, reptiles and mammals). This is seen in an extreme degree in the diverse fats of such species as the balænic whales, the sperm whales and the dolphin and porpoise family; but it also obtains to a lesser extent in those of many species of fish. This leads one on one hand to feel that Shorland may attach less importance than is necessary to the effect of species and too much to the "fortuitous influence of the diet", and on the other hand to inquire whether it is adequately established that marine animals derive all their fat from preformed dietary sources. Profound modification of dietary fat would appear essential to produce, for example, the characteristic wax-esters of the Physeteridæ or the isovaleric glycerides of the Delphinidæ.

(*b*) Shorland's intermediate stage (*b*), at which animals may acquire the ability to make 'synthetic' fat, more or less of a uniformly simple composition with palmitic, stearic and oleic acids as its main components, would seem to include a variety of species, but at the same time to exclude others which are at an equivalent or parallel stage of development. Thus fats of the type indicated, and usually rich in stearic acid, are deposited not only by ruminants but also by a wide range of other animals, including the feline tribe[1–3], the kangaroo[4], hippopotamus[4] and elephant[5]. In contrast, other equally developed animals, such as bears[2], apes[3] and human beings[6], produce fats with much higher proportions of oleic (and sometimes hexadecenoic) acid than the former group, but containing comparatively small amounts of stearic acid and sometimes less palmitic acid than the 'normal' animal fat figure[7] of 30 ± 3 per cent (mol.) of the total acids.

(*c*) It is clear that whereas ruminants produce to a major degree the simpler type of 'synthetic' fat rich in palmitic, stearic and oleic acids, the pig also normally synthesizes[8] similar kinds of 'synthetic' fat (poorer in stearic and richer in oleic acid) but is equally capable of assimilating in addition fats present in its food[9]. It has recently been shown[10] that the body fats of a pig fed freely on whale oil consisted substantially of mixtures of almost unchanged whale oil glycerides with typical 'synthetic' pig-fat glycerides.

The horse presents another instance which seems not to fit in Shorland's generalization, for as he[11] and others[12] have shown, the fat of pasture-fed horses contains notable amounts of linolenic acid apparently absorbed from the grass glycerides. It is indeed a striking example of species influence that fats of entirely different composition are produced by a horse, an ox, and a sheep feeding on the same field of pasture.

(*d*) Lastly, it should not be overlooked that the very small amounts of branched-chain acids recently shown to be present in certain animal fats may well arise, not from the true fat, but from sweat gland waxes or similar sources which have accidentally passed into the fat during its preparation from the animal tissue.

Anti-mutagens

While studying the mutagenic action of various purine derivatives on bacteria, we came across a new phenomenon: we found that certain nucleosides can act as anti-mutagens.

Following the discovery[1] that caffeine—a purine derivative—increases the mutation-rate in fungi and in bacteria, we began a quantitative study of the mutagenic action of purine derivatives. Such a study has been made possible by the use of a constant flow device, called the 'Chemostat'[2–4], which maintains a stationary bacterial population growing at a fixed rate that can be set at will. The concentration of the bacterial population maintained in the growth tube of the 'Chemostat' is determined by the input concentration of one of the required nutrients, called the controlling growth factor, and the growth-rate is fixed by the rate at which fresh nutrient flows into the growth tube.

A variety of different mutations will occur at different rates in such an otherwise stationary population, and if one plots the concentration of one

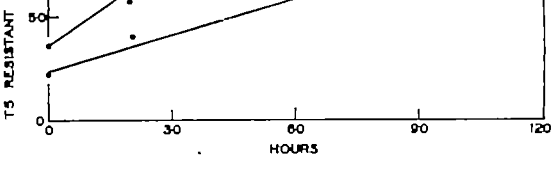

Fig. 1

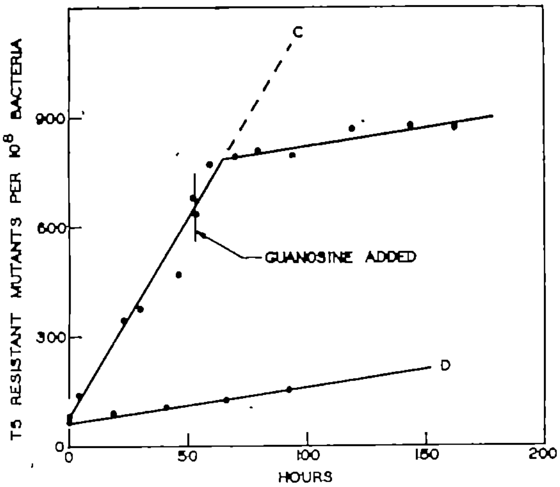

Fig. 2

particular type of mutant against time, one should obtain a straight line which rises with a slope that is determined by the mutation-rate. This holds for each type of mutant which grows at the same rate as the parent strain, that is, if there is no selection for or against the mutant. If there is selection against a mutant, the concentration of that mutant will remain stationary after an initial rise.

In the experiments to be reported here, we used a strain of *E. coli* (*B*/1*t*) requiring tryptophane, and used tryptophane as the controlling growth-factor. This organism is sensitive to the bacteriophage *T5*. Mutants resistant to *T5* present at any given time in the population growing in the 'Chemostat' can be scored by colony count simply by adding a small quantity of the virus *T5* to an aliquot at the time of plating; in the presence of the virus, only the resistant mutants will grow out into colonies.

As we reported earlier[3], mutation to *T5* resistance occurs at a constant rate independent of the rate at which the bacteria grow, that is, independent of the generation-time of the bacteria. By plotting against time the number of *T5*-resistant mutants present in the growth tube of the 'Chemostat', one obtains curve *A* of Fig. 1. The slope of this straight line gives a mutation-rate $\mu = 1 \cdot 4 \times 10^{-8}$/bacterium/hr.

When the nutrient medium contains theophylline (a dimethylxanthine) in a concentration of 150 mgm./l., the number of mutants rises very quickly, corresponding to the straight line *C* in Fig. 2, giving a mutation-rate of $10 \cdot 7 \times 10^{-8}$/bacterium/hr. This represents a seven-fold increase in the mutation-rate, which we attribute to the mutagenic action of theophylline. However, if the nutrient contains, in addition to 150 mgm./l. of theophylline, 50 mgm./l. of the nucleoside guanosine, the number of mutants rises much more slowly, as shown by line *D* in Fig. 2. The slope of this line corresponds to a mutation-rate of about 1×10^{-8}/bacterium/hr., indicating that guanosine, in the concentration used, completely counteracts the mutagenic action of the theophylline.

In the experiment mentioned earlier, which is described in the upper curve in Fig. 2, the bacterial population is first grown (at a generation-time of 3·2 hr.) in the presence of 150 mgm./l. of theophylline with no guanosine present. After 53 hr., guanosine is added to give a concentration of 150 mgm./l. For the first 53 hr. and for a short time thereafter, the number of mutants follows the straight line *C*, which gives a mutation-rate of $10 \cdot 7 \times 10^{-8}$/bacterium/hr.; but afterwards the number of mutants follows another straight line which gives a mutation-rate of less than $1 \cdot 5 \times 10^{-8}$/bacterium/hr. The two straight lines intersect, not at the time when the guanosine is added, but about 12 hr. later.

In order to explain this 12-hr. delay in the fall of the mutation-rate after adding guanosine, we do not have to assume that it takes that time for the guanosine to counteract the mutagenic effect of theophylline, but may attribute the delay to the fact that mutations are not immediately expressed in the phenotype of the bacteria. When the guanosine is added, the mutations induced by theophylline may very well cease to occur; but the mutations induced prior to the addition of guanosine continue to be expressed phenotypically for a period of about 12 hr.

The results shown in Fig. 2 have to be interpreted as an actual reduction of the mutation-rate by guanosine; that is, they cannot be attributed to a selection against the bulk of *T5*-resistant mutants resulting from the presence of guanosine. It is easy to show that if such a selection were responsible for the low mutation-rate shown by line *D* in Fig. 2, then in the upper curve in Fig. 2 the number of mutants resistant to *T5* should fall steeply after adding guanosine at the 53rd hour.

The concentration of guanosine needed to counteract the mutagenic effect of 150 mgm./l. of theophylline is quite low. For a concentration of about 2 mgm./l. of guanosine, the rate of mutation induced by theophylline falls to one-half.

The other normally occurring purine ribosides were examined for anti-mutagenic action at concentrations of 5 mgm./l. At this concentration adenosine and inosine are strongly anti-mutagenic against theophylline, whereas xanthosine has no such activity. In contrast to inosine itself, its components, that is, the free purine hypoxanthine and the free sugar ribose, are not anti-mutagenic even at concentrations of several hundred milligrams per litre.

A concentration of 500 mgm./l. of guanosine gives practically complete suppression of the mutagenic action of the following purine derivatives (at concentrations of 150 mgm./l.): theophylline, caffeine, theobromine, paraxanthine, and 8-azaguanine. But tetramethyluric acid and benzimidazole retain more than half their mutagenic effect.

One may ask what effect guanosine has on the spontaneously occurring mutations. As can be seen from line *B* in Fig. 1, 50 mgm./l. of guanosine gives a mutation-rate of $0 \cdot 6 \times 10^{-8}$/bacterium/hr., that is, one-half to one-third as much as the spontaneous mutation-rate derived from curve *A*. This shows that guanosine in the concentration used reduces the mutation-rate to *T5* resistance appreciably below the spontaneous mutation-rate.

Agglutination Reactions in Human Red Cells Fragmented by Heat

Murray and Clark[1] have shown that, if red cells are heated to 50° C., substances can be obtained from the surrounding fluid which, even if derived from *Rh*-negative red cells, can give rise to anti-*D* agglutinins when injected into guinea pigs. Temperatures in the neighbourhood of 50°–56° produce extensive modifications of the human red-cell surface, namely, fragmentation, development of myelin forms, and, at the higher temperatures, hæmolysis[2]. It is therefore likely that the substances found by Murray and Clark in the fluid surrounding the heated cells are the products of the fragmentation phenomena and the changes in the red-cell surface which accompany them.

Thrice-washed human red cells (group *O*, *CDE* positive) are heated for 10 min. at 50°, 52°, 54° and 56° C., and then tested for their reactivity with anti-*D* serum at 37° C. As the temperature is increased, the fragmentation and hæmolytic phenomena become more and more pronounced, as already described[2], and as can be seen by examining the suspensions by phase contrast. At the same time, the serological reactivity of the red cell surface becomes modified. Agglutination by 'complete' (saline agglutinin) antibody becomes progressively weaker as the temperature to which the cells are heated is increased, and is almost lost after heating to 56° C. However, cells which have been heated even to 56° C. will react with 'incomplete' (blocking) antibody, as shown by a positive indirect Coombs reaction. The cell surface is not modified to such an extent, however, as to give a positive direct Coombs reaction.

Similar experiments show that heating progressively decreases the trypsinizability of red cells, and progressively decreases the reactivity of red cells which have been trypsinized before the heating.

The material obtained by ultracentrifuging the heated preparations, that is, the material which Murray and Clark find to be antigenic in the guinea pig, consists of tiny fragments and myelin forms. The reactivity of their surfaces, however, is so reduced that no agglutination-like phenomena can be produced by the addition of anti-*D* sera.

Pseudo-Cholinesterase of Brain

Shortly after the distinction had been made between the true cholinesterase and the pseudo-cholinesterase[1,2], it was claimed that the brains of vertebrates contain true cholinesterase only[3]. This latter statement has proved to be incorrect; when large amounts of tissue are used for cholinesterase determinations, the presence of a small amount of pseudo-cholinesterase in brain can be demonstrated[4,5]. Experiments with selective inhibitors of pseudo-cholinesterase have rendered it highly improbable that this enzyme would have any important role in the hydrolysis of acetylcholine released at nerve endings[6–8]. However, the pseudo-cholinesterase in brain appears to be associated particularly with the myelinated fibre tracts of the central nervous system, and it has been suggested that the activity of this esterase may be connected with processes occurring in the myelin sheaths or neuroglial elements of the nervous system[5].

This suggestion is especially interesting in view of the fact that tri-ortho-cresyl phosphate (TOCP), which is known to be a selective inhibitor of pseudo-cholinesterase[7], causes paralysis in many species with demyelination of the peripheral nerves, degenerative changes in the anterior horn cells, and fatty degeneration in the white matter of the spinal cord[9]. Studies on the inhibition of the cholinesterases by tri-ortho-cresyl phosphate *in vitro* have been carried out recently by Earl and Thompson[10], who suggested that inhibition of the pseudo-cholinesterase by this substance might play a part in the demyelination and consequent paralysis. We have also investigated the significance of the pseudo-cholinesterase in brain along two lines in our laboratory.

First, a very detailed study on the cholinesterase activity of ox brain failed to reveal the presence of any pseudo-cholinesterase, thus confirming a previous report[11] on the absence of pseudo-cholinesterase in various other tissues of this species and of the sheep. The absence of pseudo-cholinesterase from the tissues of ruminants shows that the paralysis due to tri-ortho-cresyl phosphate, which can also be produced in ruminants[9,12,13], is not likely to be due to inhibition of pseudo-cholinesterase.

Nevertheless, we thought it necessary to substantiate this conclusion by inhibiting the pseudo-cholinesterase in a species the brain of which does contain this enzyme. Three groups of young male rats of a crossed Wistar-piebald strain, weighing between 75 and 85 gm., were used in this experiment. One group served as controls, the second group was injected subcutaneously with 0·5 ml. tri-ortho-cresyl phosphate, while the third group was injected intramuscularly with 0·05 ml. and after six weeks with 0·1 ml. of this substance. The injections were repeated every four days for three weeks, and from then on once a week for a total period of fourteen weeks. Animals were sacrificed at various times to determine the cholinesterase activities of the tissues by the methods described by Mendel *et al.*[2] and Thompson *et al.*[5,10]. The cholinesterase activities of the tissue homogenates were determined manometrically with 0·03 *M* acetyl-β-methylcholine[2] as specific substrate for the true cholinesterase, and 0·006 *M* benzoylcholine[2] and 0·03 *M* butyrylcholine[5,10] as specific substrates for the pseudo-cholinesterase. Esterase activities are expressed as μl. carbon dioxide produced per hr. per 100 mgm. tissue or per ml. serum (see table). The rats of group II were injected subcutaneously with 0·5 ml. tri-ortho-cresyl phosphate and those of group III intramuscularly with 0·1 ml. In both groups of rats treated with tri-ortho-cresyl phosphate, the pseudo-cholinesterase of brain was almost completely inhibited from the seventh day until the end of the experiment.

During this period of fourteen weeks, each of the seven remaining rats of the second group gained about 160 gm. on the average, those of the third group 300 gm. and the control animals 320 gm. Despite the complete and prolonged inhibition of the pseudo-cholinesterase in brain, none of the animals showed any signs of paralysis. The rats of the third group were indistinguishable in appearance from the controls; histological examination of the brain, spinal cord and sciatic nerves of these animals did not reveal any demyelination or other abnormalities.

INHIBITION OF THE CHOLINESTERASES OF RAT BRAIN AND OTHER TISSUES AFTER INJECTIONS OF TRI-ORTHO-CRESYL PHOSPHATE FOR 14 WEEKS

Tissue	Group No.	True cholinesterase activity	Pseudo-cholinesterase activity Benzoylcholine	Butyrylcholine
Cerebellum	control	96	8	38
	II	28	—	0
	III	52	—	0
Cerebrum	control	476	7	52
	II	133	—	0
	III	218	—	0
Thalamus, pons and medulla	control	286	26	146
	II	86	0	0
	III	185	0	2
Heart	control	29	155	830
	II	11	0	10
	III	16	10	54
Liver	control	—	37	210
	II	—	0	5
	III	—	2	18
Small intestine	control	—	184	960
	II	—	0	18
	III	—	26	148
Serum	control	160	78	416
	II	102	6	38
	III	150	16	82

Two conclusions can be drawn from these experiments. First, the integrity of medullated nerve fibres does not seem to depend on the activity of the pseudo-cholinesterase in the myelin sheaths; secondly, the pseudo-cholinesterase is not required for the hydrolysis of acetylcholine released by nervous activity in the brain.

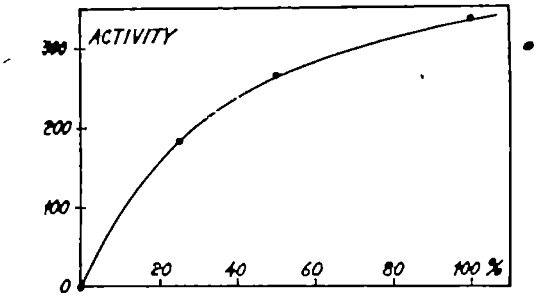
Isolation of a Soluble Fibrinolytic Activator from Animal Tissue

ANIMAL tissue contains a fibrinolytic activator (fibrinokinase) which cannot be brought into aqueous solution by the usual procedures for extracting biologically active substances[1]. This observation was confirmed by Tagnon[2] and by Lewis and Ferguson[3], who found that the microsome fraction of the disintegrated tissue was particularly active.

When bovine lung tissue was treated as described for the preparation of fibrinokinase, no fibrinolytic activator was obtained, but the tissue acted as a powerful inhibitor of trypsin and plasmin[4]. Recently[5], we succeeded in isolating from this tissue a soluble protease inhibitor by extraction with potassium thiocyanate, performed as described by Snellman, Jensen and Sylvén[6] for the isolation of heparin from animal tissue.

We have now found that a similar treatment of the insoluble fibrinokinase preparation yields the fibrinolytic activator in a water-soluble form. Thus a fibrinokinase preparation made in the usual manner from pig hearts was treated for one hour with *M* potassium thiocyanate. The tissue was removed by pressing through gauze and the solution was dialysed against diethylbarbiturate buffer (pH 7·8, $\mu = 0{\cdot}05$). The resulting solution showed a high activating power on plasminogen. The substance was obtained as a dry powder by precipitation with acetone and drying with acetone and ether, yield about 100 mgm. per gm. of crude material.



Activity (ordinate) of increasing concentrations (abscissa) of a stock solution (7 mgm./ml.) of the soluble fibrinolytic activator, recorded as the product of two perpendicular diameters of the lysed zones. Substrate: bovine fibrin containing plasminogen

The product obtained was not completely soluble in the buffer, but its solution showed a high fibrinolytic activity when tested by the usual fibrin plate method, where plasminogen is present in the substrate (see graph). On fibrin plates containing no plasminogen (prepared as described elsewhere[7]) no activity was found.

In view of this successful isolation of a soluble fibrinolytic activator from animal tissue, it might be interesting to investigate the possibility of using a solution of potassium thiocyanate in the extraction of other enzymatic substances which are found to occur preferably in the so-called mitochondria and microsome fractions of disintegrated tissue[8].

Rapid Restitution of the Rat Pancreas following Acinar Cell Necrosis Subsequent to Ethionine

ONLY rarely has the suggestion been made that the pancreas, human[1] or animal[2], possesses the faculty of complete regeneration. Ethionine, a metabolic analogue of methionine, produces acinar cell necrosis of the pancreas[3]. Rats show within one to two weeks after pancreatic acinar cell necrosis a relatively complete restitution of the organ.

Thirty-eight fasted Wistar white rats, both sexes, 160–190 gm., having access to 'Purina' chow and water were used. Fourteen were each given 50 mgm. of D-L ethionine daily in distilled water intraperitoneally for 14 days. Sixteen each received 100 mgm. of ethionine intraperitoneally daily for 10 days. Six rats were used for controls. Animals were sacrificed at 2, 4, 6, 7, 8, 10, 14, 21 and 28 days and nine months after the initial injection.

Animals sacrificed during ethionine administration showed the characteristic effect[3]. On the lower dosage, complete acinar cell necrosis was seen by the tenth day. Ducts and islets were not involved. Regeneration, indicated by cells in mitosis, or cells with deeply basophilic cytoplasm and large nuclei, was noted on the seventh day. At the fourteenth day regenerating cells were frequent and lobule formation beginning. Seven days after cessation of ethionine, normal architecture was demonstrated by discreet lobules, well-formed acini, and zymogen granules in the apical cytoplasm. Seven days later, a few cytoplasmic vacuoles in the acinar cells were the only abnormality. Weakness, and severe loss of weight, progressing from the fifth day, were followed by clinical recovery within a day or two after cessation of the drug.

With the higher dosage, effects were similar but more pronounced. By the eighth day, acinar cells had disappeared and only intact duct and islet cells, inflammatory cells and small groups of regenerating, spindle mononuclear cells were present. Four days after cessation of ethionine, many mitotic figures, incipient lobule formation and acinar cells with basal basophilia were noted. At eleven days after treatment there was restitution of normal architecture, with zymogen granules present in the acinar cell cytoplasm and frequent mitotic figures. One animal sacrificed 18 days after drug cessation showed only minimal restoration. All other animals killed one to two weeks after the cessation of the drug showed restitution of the gland. Two animals, each of which received a second course of ethionine after recovery from the initial dosage, revealed no pancreatic abnormalities nine months later. Control animals had normal organs.

The high protein and enzyme content of the pancreas, and the significance of these substances in problems of growth, differentiation and neoplasia, suggest a possible experimental use of the pancreatic recovery from the effect of ethionine in these fields. Morphological destruction and restitution of a specific cell-type following the use of an analogue provides a means of exploring facets of methionine anti-metabolites.

Acquired Resistance to Colchicine in a Strain of *Trichomonas vaginalis*

Trichomonas vaginalis Donné, 1837 can be made resistant to a variety of chemical compounds and is a suitable organism for the study of resistance, particularly as it can be maintained indefinitely in bacteria-free cultures. Moreover, it possesses a cytostome and ingests relatively large granules (for example, rice starch), and probably acquired resistance in the case of this flagellate does not depend on non-transit of a particular compound through the surface membrane as is apparently the case in resistant trypanosomes. Thus a strain of *T. vaginalis* was made resistant to 4.4′-diamidino stilbene. Initially the strain tolerated not more than 1 in 70,000; but by culturing repeatedly on gradually increasing concentrations, a strain was obtained which grew in a concentration of 1 in 5,000. 4.4′-Diamidino stilbene fluoresces in ultra-violet light, and it was easy to demonstrate its presence in the cytoplasm of resistant flagellates grown on a concentration of 1 in 5,000[1]. On the other hand, we failed to make an Indian strain of *Leishmania donovani* and a Sudan strain of *L. infantum* resistant to this drug by the usual method of subculturing in gradually increasing concentrations.

In view of the well-known effect of colchicine on mitosis, it was considered interesting to attempt to make *T. vaginalis* resistant to colchicine. Initially our strain grew in a concentration of 1 in 16,000 colchicine incorporated in the medium, but there were only a few survivors in flagellates inoculated into medium containing 1 in 11,000. After culturing on gradually increasing concentrations for a period of almost twenty-six months (September 9, 1949–November 22, 1951) a strain was obtained which has grown on a concentration of 1 in 600 during the last four months (in thirty-two passages).

During this work a number of strains, after having been established on particular concentrations, were maintained on colchicine-free medium for various periods and were then tested to determine whether they still maintained their resistance. The results were as follows:

Four strains were made resistant respectively to 1 in 3,000 (first grown on December 27, 1950, and maintained on this concentration for forty-five passages until May 17, 1951), to 1 in 2,000 (first grown on February 18, 1951, and maintained on this concentration for twenty-four passages until May 17, 1951), to 1 in 1,600 (first grown on May 11, 1951, and maintained on this concentration for only two passages until May 17, 1951), to 1 in 1,300 (first grown on June 6, 1951, and maintained on this concentration for twenty-seven passages until September 24, 1951), and were all kept on colchicine-free medium after the second of the above indicated dates.

On February 7, 1952, after the first three of the above strains had been grown for almost nine months (seventy passages) and the fourth for four and a half months (thirty-six passages) on normal medium, they were tested on their respective concentrations of colchicine and all gave rich normal cultures.

In the early passages, after transition from a lower to a higher concentration, cultures contained, apart from normal flagellates, large round multinuclear forms about 30 μ in diameter (these forms occur rarely in normal cultures); but in further passages the flagellates appeared normal in every respect. The temporary appearance of large round multinuclear forms in considerable numbers during the process of selecting resistant strains by subjecting *T. vaginalis* to progressively increasing concentrations is not peculiar to colchicine, for it also occurs in similar circumstances in the case of 4.4′-diamidino stilbene.

The above observations show that a strain of *T. vaginalis* was made resistant to concentrations of colchicine far beyond the maximum tolerated original dose, and that the resistance persisted after a considerable period of growth on colchicine-free medium.

We have to thank Dr. Anna Weizmann, of the Weizmann Institute, Rehovot, for preparations of pure colchicine from *Colchicum hierosolymitanum* Feinbr.

Mode of Action of Chloramphenicol

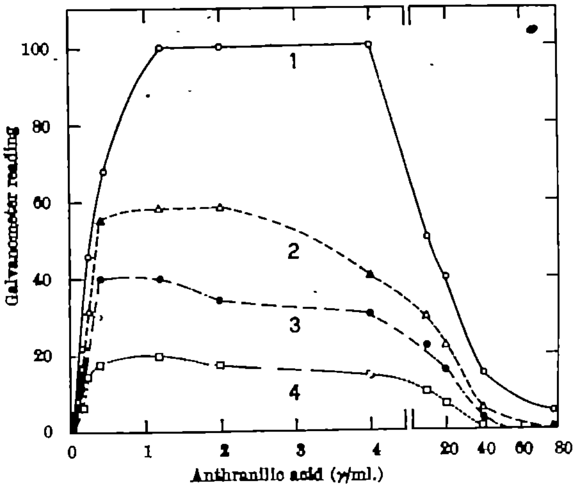
According to Woolley[1], chloramphenicol inhibits the utilization of phenylalanine in *E. coli*, due to its structural resemblance to that amino-acid. Truhaut, Lambin and Boyer[2], on the other hand, have concluded from experiments with *E. typhi* that the antibiotic interferes in the early stages of the synthesis of tryptophane, which Fildes[3] has formulated as follows:

anthranilic acid → indole
indole + serine → tryptophane.

In an attempt to elucidate the mode of action of chloramphenicol, its effect on *E. coli*, wild type, and on a number of its mutants, has been investigated. The inhibition caused in *E. coli*, wild type, can be fully reversed by indole and DL-tryptophane, less easily by DL-phenylalanine and L-tyrosine; it is not reversed by anthranilic acid. This result tends to show that chloramphenicol interferes with the synthesis of indole from anthranilic acid. The study of the mutants of *E. coli* clarifies the point still further.

In the anthranilic acid mutant (121–35), small quantities of anthranilic acid reverse the inhibition caused by chloramphenicol (up to 60 per cent of full growth), whereas larger doses inhibit growth (see graph). In the indole mutant (19–2), the inhibition is reversed by indole. In the tryptophane (19–2), phenylalanine (*M*83–5) and tyrosine (83–9) mutants, the inhibition is only reversed by the respective amino-acids if it is caused by low concentrations of chloramphenicol (1·2 γ/ml.).

The completeness of the reversal effects decreases from the indole mutant to the tyrosine mutant; this, incidentally, appears to point to a scheme for the interrelationship of the three aromatic amino-acids in which phenylalanine and—still more—tyrosine are further removed from the point of the attack of the antibiotic than tryptophane, that is:



Reversal of chloramphenicol inhibition by anthranilic acid in *E. coli* mutant requiring anthranilic acid. Incubated: 18 hr. at 37°. Curve 1: no chloramphenicol; curves 2, 3, 4. 1·2, 1·6 and 2·0 γ/ml. of chloramphenicol, respectively

precursor → tryptophane → phenylalanine → tyrosine[4].

The question of the mechanism by which indole is synthetized from anthranilic acid does not seem to have been investigated. The hypothesis that N-formylanthranilic acid is the intermediate product has been tested in view of previous experience with 4-formamido-imidazole-5-carboxamide[5] and of the observations of Knox and Mehler[6] on the transformation of tryptophane into kynurenine via formylkynurenine; however, N-formylanthranilic acid was inactive. In *E. coli*, wild type, the inhibition by chloramphenicol is overcome by the combination of anthranilic acid with methionine and vitamin B_{12} (see table). Folic acid was inactive, and *p*-amino-benzoic acid showed a negligible activity, when used in conjunction with anthranilic acid and methionine. All other—normal—'methyl donors' were completely ineffective, only histidine showing a very slight activity.

Analogously, the inhibition caused by chloramphenicol in the anthranilic acid mutant could be reversed by the addition of vitamin B_{12} or methionine, or the system vitamin B_{12} plus homocystein; the latter alone proved completely ineffective.

The methyl group of methionine has also been found to be the sole source of a 'lone' carbon atom in the biosynthesis of purines[7] and in the biosynthesis of nicotine in the tobacco plant[8].

The observation that larger quantities of anthranilic acid inhibit the growth of the mutant requiring anthranilic acid suggests that this amino-acid is not the immediate precursor of indole. The

Reversal of Chloramphenicol Inhibition in *E. coli*, Wild Type

possibilities that N-methyl-anthranilic acid, an N-glycosido-anthranilic acid, or a peptide of anthranilic acid are intermediates in the conversion of anthranilic acid to indole, are now being investigated. The ability of the cell to synthetize peptides of anthranilic acid is demonstrated by the structure of certain alkaloids, for example, of the antimalarial alkaloid in *Hydrangea*[9] and of delsemin in *Delphinium oreophilum*[10].

The mutants used in this investigation were kindly supplied by Dr. B. D. Davis.

Hypotensive Alkaloids of *Veratrum album*

INVESTIGATIONS on alkaloids of *Veratrum viride* necessitated the preparation of a pure specimen of protoveratrine and prompted an examination of the alkaloids which could be isolated from commercial samples of *Veratrum album*. As a result of these studies, we now report the isolation of two new hypotensive ester alkaloids which have been named 'germitetrine' and 'veratetrine'.

Extraction of commercial *Veratrum album* and crystallization of the crude product from ether according to the method described by W. A. Jacobs and L. C. Craig[1] yielded a crystalline fraction which was subjected, without further purification, to a 24-plate Craig counter-current distribution, using benzene and 2 *M* acetate buffer at *p*H 5·5 as the immiscible phases.

From tubes 17–24 of the above Craig distribution, protoveratrine was isolated (m.p. 270–271° with decomp. (cor.); $[\alpha]^{25}_{D}$, – 35·9° (con. 1·0 in pyridine); $[\alpha]^{25}_{D}$, – 10·9° (con. 1·0 in chloroform); calculated for $C_{44}H_{61}O_{13}N$; C, 62·28; H, 8·18; found: C, 61·70; H, 7·78 per cent). The material was further identified as protoveratrine by degradation studies. Hydrolysis at room temperature in presence of methanolic sodium hydroxide yielded the alkamine isoprotoverine (isolated and characterized by melting point, analysis and ultra-violet absorption spectrum) and an acidic fraction. The acidic fraction was treated with *p*-phenyl phenacyl bromide, and the resulting mixture separated chromatographically into the *p*-phenyl phenacyl esters of acetic acid, α-methyl butyric acid and methyl ethyl glycollic acid, using methods similar to those described by J. Fried, H. L. White and D. Wintersteiner[2].

The material recovered from tubes 10–15 was crystallized from benzene and yielded germitetrine (m.p. 229–230°; $[\alpha]^{25}_{D}$, – 74° (con. 1·0 in pyridine); $[\alpha]^{25}_{D}$, – 12° (con. 1·0 in chloroform)). Analytical data indicate the empirical formula $C_{41}H_{63}O_{14}N$; (calculated, C, 62·00; H, 7·92; N, 1·80; found: C, 62·01, 61·88; H, 7·89, 7·77; N, 1·37, 1·37 per cent); calculated equivalent weight, 794; found, 780. Germitetrine has a characteristic infra-red spectrum which differs from the spectra of protoveratrine and veratetrine. Alkaline hydrolysis of germitetrine and examination of the hydrolysis products by the methods indicated above has yielded the alkamine germine, together with the *p*-phenyl phenacyl esters of acetic acid, α-methyl butyric acid and a third unidentified acid. The *p*-phenyl phenacyl ester of the unidentified acid crystallized from ethanol in white needles (m.p. 163–164° (cor.)). Volatile acid determinations gave 2·8–3·02 equivalent of volatile acid and would indicate that the unidentified acid is non-volatile, since other evidence suggests that germitetrine is a tetra-ester containing two moles of acetic acid, one mole of α-methyl butyric acid and one mole of unidentified acid in combination with one mole of the alkamine germine.

From tubes 0–9 of the Craig distribution, veratetrine was isolated (m.p. 269–270° (dec.); $[\alpha]^{25}_{D}$, – 32° (con. 1·0 in pyridine); $[\alpha]^{25}_{D}$, – 6·8° (con. 2·0 in chloroform). The analytical data indicate the empirical formula $C_{43}H_{64}O_{16}N$; (calculated, C, 60·7; H, 7·58; N, 1·6; equiv. weight, 850·5; found, C, 60·1; H, 7·50; N, 1·4 per cent; equiv. weight, 839). Alkaline hydrolysis of veratetrine and examination of the hydrolysis products by the usual methods has afforded isoprotoverine and the *p*-phenyl phenacyl esters of α-methyl butyric acid, acetic acid and an unidentified acid.

This work will be described in greater detail in a forthcoming publication.

Transport of Substances through the Tentacles of Leaves of *Drosera capensis* L.

IT was found by Darwin[1] that the tentacles of *Drosera* secrete a viscous liquid with their glands, that they curve after stimulation and that they absorb substances from the animals caught. The processes of uptake and transport have been extensively studied in my laboratory[2,3,4]. The marginal tentacles of a cut leaf are put between strips of agar which contain the substance to be absorbed. The tentacles translocate it in their pedicels to the leaf. The curving of the tentacles which would move them out of the agar can be prevented by adding an osmotic substance (sugar or salt) to the agar. This reduces the turgor of the tentacles so that they cannot curve.

The uptake of different substances was determined with simple methods: phosphate colorimetrically and nitrogen by micro-Kjeldahl method. The uptake of all substances depends more or less on the presence of oxygen. The results given here relate only to a class of actively absorbed substances, by which we understand that in the absence of oxygen no absorption takes place at all (this is only valid in sufficiently low concentrations).

Two groups of actively absorbed substances have been investigated: (1) inorganic phosphates; (2) amino-acids (asparagine and glutamine). The substances are only absorbed at low concentrations. A maximum level of uptake is attained at a rather low concentration. Experiments with simultaneous uptake of two substances show that, if substances of the same group are combined, summation results until the maximum level of uptake for that group is attained. If substances belonging to different groups are combined, the summation goes on until the maximum level is attained for each substance. This indicates that in the uptake of the two groups of substances different metabolic processes are involved.

These results have been confirmed by new observations with enzyme inhibitors. The inhibiting substances were applied in the agar which contained the transport substance. Substances inhibiting respiration (cyanide, azide, iodoacetate and arsenite) diminish the uptake of substances of both groups. Likewise, 2-4 dinitrophenol has an unspecific inhibitory function (Table 1). Some inhibitors were found to be more specific. For example, phloridzin inhibits the transport of phosphate but not that of asparagine, whereas penicillin inhibits the transport of asparagine but not that of phosphate (Table 2). The specific action is in good agreement with the assumption that the absorption of phosphates depends on different metabolic processes from that of amino-acids, but both depend on respiration.

EFFECT OF INHIBITORS ON THE UPTAKE OF ASPARAGINE AND PHOSPHATE BY THE TENTACLES OF *Drosera* LEAVES, IN PARTS PER 1,000 PARTS OF FRESH WEIGHT OF THE LEAVES

1. Non-specific inhibitor (2-4 dinitrophenol)		
	24-hr. uptake of 1/100 *M* asparagine (nitrogen)	24-hr. uptake of 1/80 *M* pot. dihydrogen phosphate (phosphate)
Without inhibitor	1·00	0·50
2-4 Dinitrophenol 10^{-7} *M*	0·74	0·40
2-4 Dinitrophenol 10^{-6} *M*	0·19	0·07
2-4 Dinitrophenol 10^{-5} *M*	−0·01	−0·07
(2) Specific inhibitor (penicillin)		
	24-hr. uptake of 1/100 *M* asparagine (nitrogen)	48-hr. uptake of 1/200 *M* pot. dihydrogen phosphate (phosphate)
Without inhibitor	1·35	0·75
Penicillin, 1 O.U./ml.	1·16	0·75
Penicillin, 2 O.U./ml.	0·74	0·77
Penicillin, 4 O.U./ml.	0·58	0·76

The specific action of penicillin on amino-acid uptake by *Drosera* tentacles reminds us of the inhibition investigated by Gale of the uptake of glutamic acid in growing cells of *Staphylococcus aureus*[3].

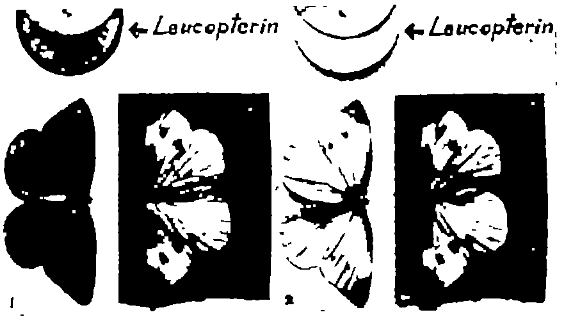
Sex in *Pieris rapae* L. and the Pteridin Content of their Wings

WHEN *Pieris rapae* L. was photographed under the illumination of ultra-violet light passing through the filter *UV-D*1 obtained from the Matsuda Lamp Co., the wings of female butterflies, in accordance with the description of Frank Lutz[1], showed a white image, for they reflected the light, whereas those of male butterflies gave a black shadow because they absorbed the ultra-violet light strongly, as seen in the accompanying photograph (Fig. 1); this is in striking contrast to photographs taken in daylight (Fig. 2). Experiments carried out to elucidate the mechanism of this phenomenon showed that it is due to the difference of pterin content between the male and the female wings.

Under ultra-violet light passing through the filter *UV-D*1, the male insects showed an intense dark vermilion fluorescence, whereas the female wings gave only a very faint pale fluorescence.



When an aqueous suspension of a small quantity of powdered leucopterin was filtered through a small filter paper and the residue with the filter paper was photographed under the illumination of ultra-violet light, it showed the same black shadow as that of the male wings (see Fig. 1). The leucopterin had under ultra-violet light the same vermilion fluorescence as the male wings.

A chemical analysis of the wings of *Pieris rapae* L. was then carried out. Equal numbers of the wings of female and male insects, after washing with ether, alcohol and then with water, were extracted with dilute ammonia. The extracts were then evaporated to a small volume, when two kinds of white deposits settled out from the extract of male wings, while a very small amount of precipitate was found in the case of the female wings only after concentration to a very small volume. The first precipitate from the extract of male wings was identified as a mixture of leucopterin with a small quantity of uric acid by comparison with the synthetic samples on paper chromatography[2], and by ultra-violet absorption spectra, while the second (a small quantity) consisted of uric acid and xanthopterin *a*[3]. The precipitate extracted from the female wings consisted of xanthopterin *b*, which was identified by its R_F and a deep purple fluorescence under ultra-violet light on paper chromatography[4].

The filtrates of the above precipitates showed on paper chromatography in the case of male wings spots of leucopterin, xanthopterin *a* and a trace of xanthopterin, and in the case of female wings spots of xanthopterin *b* and a trace of xanthopterin.

Generally speaking, the pterin content of female wings is very small in contrast with that of male wings.

Diurnal Variations in the Blood Picture of Cattle

CATTLE bloods were examined at intervals during the course of the day at Kabete, Kenya, altitude 6,300 ft., the maximum temperature at the season of the experiment being greater than 75° F., the minimum less than 52° F. The cattle were Zebu/European cross. Water was given them at one point while the experiments were in progress but did not affect the results. Blood was drawn from the jugular vein into oxalated tubes, prepared according to Wintrobe[1]. The neck was constricted with a rope while the vein was entered, but released while the blood sample was being drawn. Blood was drawn at hourly intervals between 9·0 a.m. and 3.0 p.m.

Hæmoglobin figures (estimated by Sahli) varied little and may be regarded as usually constant. The normal variation did not exceed 1 gm. per 100 c.c.

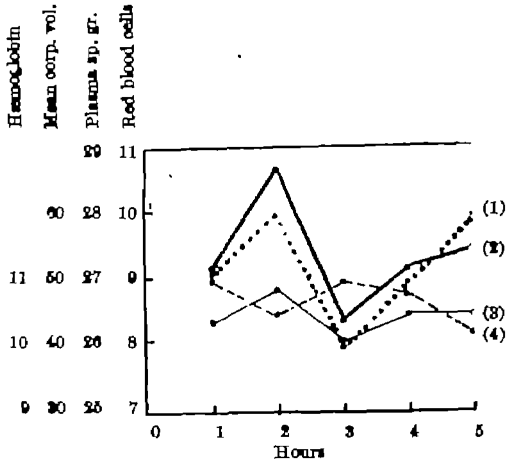

Fig. 1. No. 3237. (1) Specific gravity of plasma; (2) red blood cells (millions/c.mm.); (3) hæmoglobin (gm./100 c.c.); (4) mean corpuscular volume (c.μ)

The red-cell count varied over two million on initial counts of seven million to ten million. Maximum variations of the packed cell volume occurred of 6 per cent (that is, per cent red cells of whole blood) on initial figures of 37–48 per cent; mean corpuscular volume showed variations in most cases, the greatest change being from 47 to 59 c.μ. Mean corpuscular hæmoglobin showed variations of as much as 3 γγ on initial readings of 12 γγ and mean corpuscular hæmoglobin concentration of 3 per cent on initial figures of 21–27 per cent. Plasma specific gravity varied within wide limits, a fall from 1·028 to 1·025 being recorded. Blood specific gravity figures had no significance, owing to the changes of specific gravity of plasma; the difference between the specific gravity of the blood and plasma, however, showed wide variation.

Estimations of dry weight of plasma samples have shown that plasmas of high specific gravity contain a greater percentage of dry matter. The fall of specific gravity is therefore due to dilution of the plasma with fluid.

The following correlations were found: (1) between the red cell count and the specific gravity of the plasma; (2) inversely both between red blood cells and mean corpuscular hæmoglobin, and between packed cell volume and mean corpuscular hæmoglobin concentration; (3) between packed cell volume and the specific gravity of the plasma; (4) inversely between mean corpuscular volume and the specific gravity of the plasma; (5) the difference between blood and the specific gravity of the plasma is inversely related to the red cell count.

Some of these changes in the case of one animal studied are shown in the accompanying charts.

The key to these changes must lie with the variation of the specific gravity of the plasma. The hæmoglobin content of the blood is maintained at a constant level; but fluid added or abstracted alters the ratio of cells to plasma. In many cases, the fall of plasma specific gravity is greater than that of red cells, showing that in spite of a reduction of the red cell count there are more red cells in the circulating blood. Changes in the size of the red cells are presumed to be due to alterations of osmotic pressure. Some change of mean corpuscular hæmoglobin concentration would be expected, due to changes of size of red cells. Changes of mean corpuscular hæmoglobin, however, reveal a mechanism in which the quantity of hæmoglobin in the individual cell may be varied. The mean corpuscular hæmoglobin is in inverse proportion to the red cell count, but related to the difference between the specific gravity of the blood and plasma. It follows that the weight of the red cells is proportional to their hæmoglobin content.

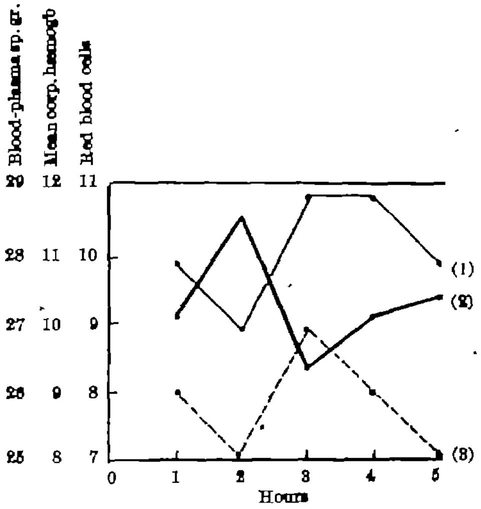

Fig. 2. No. 3237. (1) Mean corpuscular hæmoglobin (γγ); (2) red blood cells (millions/c.mm.); (3) difference between specific gravity of blood and plasma

The object of this work was achieved when the diurnal variations were demonstrated, and it will probably not be further pursued. It is evident that workers should not attach too much weight to variations in the blood picture of cattle under African conditions. Other implications are involved, namely, the variation of the fluid content of the circulating blood. This may be due to the action of the liver on water metabolism, and reference may be made to Lichtman's work[2], who describes this effect.

It is possible that a study of the control of water metabolism, suggested by this work, may be of importance to an understanding of the physiology of cattle in hot climates or in times of drought.

Vapour-Liquid Equilibrium Relationships in Extractive Distillation

THE advantages of using binary data to calculate the effect of a high-boiling solvent on the volatility of a pair of liquids have frequently been emphasized. Recently, a thermodynamic method of calculating the average value of the logarithm of the volatility ratio of the low-boiling pair (components 1 and 2) at a constant mole fraction of the high-boiling solvent (component 3) under isothermal conditions from binary data has been advanced[1]. A treatment of this type has now been developed for single liquid-phase systems under a pressure of one atmosphere and the following approximate expression obtained:

$$[\log \bar{\alpha}_{12x_3}]_{x_3',\text{ isobaric}} \approx 4\cdot559\ [\Delta T_{21} + (\Delta T_{23} - \Delta T_{13})/x_3']/T \qquad (1)$$

These terms have the following significance: $[\log \bar{\alpha}_{12x_3}]_{x_3',\text{ isobaric}}$ is the average value of the logarithm of the volatility ratio of component 1 with respect to component 2 at a constant mole fraction, x_3', of the high-boiling solvent taken from the composition $x_1 \rightarrow 0$ to $x_2 \rightarrow 0$ under isobaric conditions. Thus this quantity is defined by equation (2), where the integral on the right-hand side is to be taken for a pressure of one atmosphere and for a constant mole fraction, x_3', of component 3.

$$[\log \bar{\alpha}_{12x_3}]_{x_3',\text{ isobaric}} = \left[\int_0^{1-x_3'} \log \alpha_{12x_3} dx_1\right]/(1-x_3') \qquad (2)$$

ΔT_{21} is the normal boiling point of pure component 2 minus the normal boiling point of pure component 1, in degrees Celsius; ΔT_{23} is the normal boiling point of the mixture of components 2 and 3 containing a mole fraction x_3' of the extractive solvent 3, minus the normal boiling point of pure component 2, in degrees Celsius; ΔT_{13} is the normal boiling point of the mixture of components 1 and 3 containing a mole fraction x_3' of the extractive solvent 3, minus the normal boiling point of pure component 1, in degrees Celsius; T is the mean of the normal boiling points in degrees absolute of the mixtures (1,3) and (2,3) containing a mole fraction x_3' of component 3.

For many systems the value of $[\log \bar{\alpha}_{12x_3}]_{x_3',\text{ isobaric}}$ will be found to be nearly equal to that of the logarithm of the volatility ratio of component 1 with respect to component 2 in the mixture containing equal mole fractions of components 1 and 2 and a mole fraction x_3' of component 3.

Previously, it was shown[1] that for isothermal data the most satisfactory third component will, in general, be that material which yields the largest numerical value of the function $[\log \bar{\alpha}_{12x_3}' - \log \bar{\alpha}_{12}]$, where the pure substance 1 is the component with the highest vapour pressure and where $\log \bar{\alpha}_{12}$ is the average value of $\log \alpha_{12}$ for the binary (1,2). From expression (1) it follows that, subject to the approximations used, the most satisfactory third component at a given mole fraction x_3' is that material which gives the largest numerical value for the expression $(\Delta T_{23} - \Delta T_{13})/T$.

The derivation of expression (1) is based on a rigorous thermodynamic treatment, but it involves many additional assumptions, of which the following are some of the more important. The vapours have been assumed to behave as ideal gases and the molar volume of the liquids has been assumed to be negligible compared with that of the vapour. The vapour pressure of the extractive solvent has been assumed to be negligible at the normal boiling temperatures of the mixtures (1,3) and (2,3) containing a mole fraction x_3' of component 3. The activity coefficients in the binary (1,3) have been assumed to obey the relationships $\log \gamma_1 = C_1(x_3')^2$; $\log \gamma_3 = C_1(1 - x_3')^2$, where C_1 is a constant. Equations of a similar type involving a constant C_2 have been assumed to be applicable to $\log \gamma_2$ and $\log \gamma_3$ in the mixture (2,3). A term on the right-hand side equal to $\left[\int_{T_{23}}^{T_{13}} (\Delta H/T^2)\mathrm{d}T\right]/2\cdot303R(1 - x_3')$ has been neglected in the derivation of expression (1), where ΔH is the molar heat of mixing of the mixture containing x_1, x_2 and x_3' mole fractions of components 1, 2 and 3, and T_{13}, T_{23} are the normal boiling points on the absolute scale of mixtures (1,3) and (2,3) containing a mole fraction x_3' of component 3. The latent heats of vaporization of the pure components 1 and 2 and of these materials from the binary mixtures (1,3) and (2,3) have been assumed to satisfy Trouton's rule.

Application of expression (1) to the experimental results for seven systems and a total of nineteen concentrations of third component where the experimental values of $[\log \bar{\alpha}_{12x_3}]_{x_3',\text{ isobaric}}$ varied from 0·05 to 0·44 showed a standard deviation of 0·043 units between the calculated and observed figures. This value is equivalent to a deviation of approximately 10 per cent in the anti-logarithm of $[\log \bar{\alpha}_{12x_3}]_{x_3',\text{ isobaric}}$.

Although a considerable number of assumptions is made in the derivation of expression (1), and although this expression is only approximate, nevertheless it is thought that this relationship is sufficiently accurate for use in the preliminary selection of the most suitable solvent for the separation of a given binary (1,2). The small amount of experimental measurement required for use in expression (1) is an attractive feature of this treatment.

This work has been carried out as part of the programme of the Chemistry Research Board, and is published by permission of the Director, Chemical Research Laboratory.

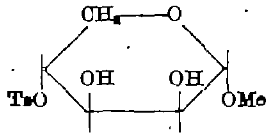
4-Deoxy-L-Ribose

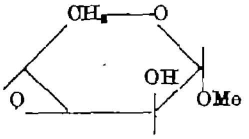
Recent investigations[1] of the behaviour of the Dische reagent[2] towards various deoxysugars and their glycosides have revealed that a coloration is obtained with a number of such compounds, and that the reagent cannot be regarded as specific for 2-deoxyribose. Colorimetric evidence based on the Dische test thus does not preclude the occurrence of deoxysugars other than 2-deoxy ribose[3] in the deoxypentose nucleic acid structure. As an extension to the investigations on the known 2-deoxyribose[4] and 3-deoxyribose[5] (otherwise known as 3-deoxyxylose), we have synthesized 4-deoxy-L-ribose, with a view to its characterization and the study of its behaviour towards colorimetric reagents.

3 : 4-Anhydro-α-methyl-D-lyxoside (II) was formed by treatment of 4-tosyl-α-methyl-D-lyxoside (I) with sodium methoxide. Scission of the ethylene oxide ring with hydrogen bromide in acetone was expected to yield two derivatives[6], 4-bromo-α-methyl-D-lyxoside (III) and 3-bromo-β-methyl-L-xyloside (IV), although, in fact, only the 4-bromo compound was isolated. Hydrogenation of the latter (III) in the presence of Raney nickel led to the glycoside of the required compound.

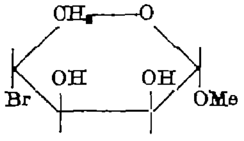
α-Methyl-lyxoside was shaken for 12 hr. with acetone containing concentrated sulphuric acid. After neutralization and removal of the solvent, 2 : 3-acetone-α-methyl-D-lyxoside was distilled as a viscous syrup (b.p. 65°/0·02 mm.; n^{21}_{D}, 1·4575). This compound reacted readily with *p*-toluenesulphonyl-chloride in pyridine to give crystalline 4-tosyl-2 : 3-acetone-α-methyl-D-lyxoside (m.p. 96–97°; $[\alpha]^{22}_{D}$, − 10·2° in ethanol (con., 1·85)). When warmed with dilute acetic acid the isopropylidene group was removed and 4-tosyl-α-methyl-D-lyxoside ($[\alpha]^{21}_{D}$, + 30·0° in chloroform (con., 1·4); n^{21}_{D}, 1·5140) resulted. Mild alkaline hydrolysis of this 4-tosyl derivative yielded 3 : 4-anhydro-α-methyl-D-lyxoside (b.p. 115° (bath temp.)/0·02 mm.; $[\alpha]^{22}_{D}$, + 98·6 in acetone (con., 1·4)). The anhydro ring was cleaved when this compound was boiled with hydrogen bromide in acetone for 4 hr., and crystalline 4-bromo-α-methyl-D-lyxoside (III) (m.p. 134–135°) was obtained. Evidence for the structure of this compound was obtained from its ready oxidation by lead tetra-acetate in glacial acetic acid[7]. Reduction of (III) with hydrogen in the presence of Raney nickel and calcium hydroxide at room temperature and atmospheric pressure gave 4-deoxy-β-methyl-L-riboside ($[\alpha]^{21}_{D}$, + 89° in water (con., 0·22)), which was hydrolysed by dilute aqueous acid to 4-deoxy-L-ribose (V) ($[\alpha]^{21}_{D}$, + 23 in water (con., 0·2); n^{22}_{D}, 1·4920) which gave a crystalline α-benzylphenyl hydrazone (m.p. 102–103°).



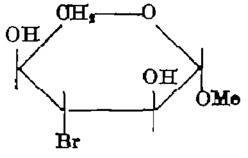
(I)



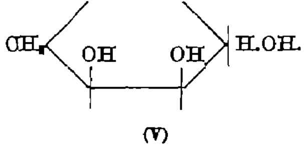
(II)



(III)



(IV)



(V)

Comparative Dische tests[2] performed simultaneously on 2-, 3- and 4-deoxyribose revealed that no coloration was given by the 4-deoxy compound or by ribose itself.

The chromatographic R_G values[8] of the three deoxyriboses were determined in butanol (40 per cent), ethanol (10 per cent), water (50 per cent) on Whatman No. 1 paper giving the following figures: 2-deoxyribose, 0·50; 3-deoxyribose, 0·60; 4-deoxyribose, 0·53.

The structure of this 4-deoxy compound involves certain problems of nomenclature, since the penultimate carbon atom is, in this case, symmetrical. We propose, therefore, that the configuration of this type of compound be decided by reference to the ultimate *asymmetrical* carbon atom, and in this instance the compound is therefore named '4-deoxy-L-ribose'.

We wish to thank Sir Rudolph Peters for his interest in these investigations.

Modified Newtonian Systems

To the usual assumptions for Newtonian mechanics, we add the following, in order to account for the behaviour of light:

(1) The speed of light is the same in all directions, relative to the emitting source.

(2) If a source moves with constant velocity, relative to a Newtonian origin, the speed of light emitted along the line of motion is the same relative to the origin or the source.

From these two additional assumptions, it is possible to develop transformation equations for two Newtonian frames S and S'. We take V as the velocity of S' relative to S and c the speed of light relative to an emitting source considered fixed in S'. If accented co-ordinates are referred to S' and unaccented to S, we have the following equations

$$\alpha x' = x - Vt, \quad y = y', \quad z = z', \quad \alpha t' = t - Vx/c^2,$$

where

$$\alpha(V)\,\alpha(-V) = 1 - V^2/c^2.$$

The simplest values of α are $(1 + V/c)$, $(1 - V/c)$ and $(1 - V^2/c^2)^{1/2}$. The Lorentz–Einstein relative velocity formula is independent of α, and so experiments which are interpreted on this formula cannot be used to choose a suitable value of α. As a preliminary, however, phenomena requiring simple kinematics have been treated. A direct explanation of the Doppler effect gives $\alpha = 1 \pm V/c$ rather than $(1 - V^2/c^2)^{1/2}$.

With this value for α the formula for stellar aberration is derived. Instead of the usual $\sin \delta\theta = \frac{V}{c} \sin \theta$, it is found that

$$\sin \delta\theta = \frac{V}{c} \sin \theta \; (1 + \cos \theta).$$

There is a large discrepancy in these formulæ when θ is near $\pi/3$, and it is suggested that an experimental check should be made.

The transformation equations can be generalized without much difficulty and give at once the general Doppler formula.

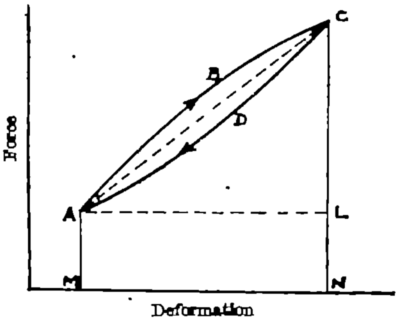
Hysteresis in Rubber

In the discussion following a recent series of lectures given in the University of Nottingham on the dynamic properties of rubber, it became evident that the methods of specifying and measuring the amount of hysteresis in rubber are subjects of controversy. Two terms in current use for specifying hysteresis are 'percentage damping' and 'resilience', as defined in the accompanying diagram.



$$\text{Percentage damping} = \frac{\text{area } ABCD}{\text{area } ABCL} \times 100$$

$$\text{Resilience} = \frac{\text{area } ADCNM}{\text{area } ABCNM} \times 100$$

Resilience is thus the ratio of energy output to energy input during one complete cycle, but the physical significance of the term percentage damping is more obscure. The two terms are complementary only if the loop starts from zero strain. Resilience is generally measured by means of a rebound pendulum in which the cycle starts from zero strain, and as a result resilience and percentage damping are almost universally considered to be complementary. It should be stressed, therefore, that when a cycle is superimposed on a static strain, the terms are no longer complementary. Such cycles can be recorded on a Roelig machine[1] and also on the machine in use at this University, details of which are in course of publication. Investigations carried out with this machine show that the hysteresis loop changes in slope and area as the static strain is varied. This means that resilience at zero static strain cannot be converted to resilience at some finite static strain simply by including an additional area such as $ALNM$. Resilience or percentage damping must therefore be measured under the conditions in which the rubber is to be used.

It has also been found that resilience is very much a function of both frequency and amplitude. The latter result means that the use of a rebound pendulum to measure resilience is fundamentally unsound, though the figure obtained from such an instrument may not be much in error.

As to the relative merits of the two terms resilience and percentage damping, the former gives a figure of considerable practical importance, and is therefore likely to appeal to the rubber user. One unfortunate feature, however, is that the rubber technologist has given the term resilience a meaning different from that given by engineers. The latter consider resilience as the energy stored in a material in the strained state.

For comparing the mechanical behaviour of two rubbers, or of one rubber under different conditions, the term percentage damping is better, since it will reveal small differences which would be masked by using resilience. That is, a small change in the area of the hysteresis loop results in a much smaller percentage change in resilience than in the term percentage damping. It should be stressed, however, that the term percentage damping as defined by Roelig[2] is the ratio of the area of the loop to the area $ABCL$ and not to the area of the triangle ACL. Roelig, in his earlier paper[1], used the area of the triangle, and many investigators since have followed this practice. The use of the triangle has several drawbacks and can lead to much ambiguity when the ends of the loops are very rounded or when the major axis of the loop is curved.

'Detectivity': the Reciprocal of Noise Equivalent Input of Radiation

There is a perfectly sound and well-known way of stating the ability of a radiation detector to detect weak signals. One simply states the amount of input radiation that produces a steady electrical output equal to the root-mean-square noise voltage, under conditions of measurement that are stated adequately. But unfortunately the noise equivalent input suffers from a crippling psychological defect: it is upside down—the better detector has a lower noise equivalent input.

Because of this psychological defect, one frequently hears the relative performance of detectors described by a statement such as: 'Detector A has a better signal-to-noise ratio than detector B'. This use of the signal-to-noise concept involves, of course, a logical confusion. The signal-to-noise ratio is a combined property of a detector and a signal, whereas the intent of the above sentence was to describe a property pertaining only to the detector.

To this difficulty there is one solution, and I believe only one solution, which is sound both psychologically and logically. The solution is to introduce as an independent concept the reciprocal of the noise-equivalent radiation input, and to give this concept a name. For some time now I have been using the name 'detectivity' for the reciprocal of the noise equivalent input, and I now propose this term for general use. With this concept the sentence discussed above becomes simply, 'Detector *A* has more detectivity than detector *B*'.

The need for this concept was set forth in an unpublished report dated March 18, 1950; in the report I suggested the terms 'detectity' or 'recinepity' for the concept and asked for better suggestions. In a reply dated July 20, 1950, Dr. Peter B. Fellgett suggested the term 'detectivity', which I now prefer.

'Detectivity' is a very appropriate name for this concept. It is self-descriptive, and it matches the companion terms 'sensitivity' and 'responsivity'; it is translated easily into other languages. The primary disadvantage is that it uses as basis the word 'detective', which is usually employed with another significance.

In summary, a need exists for a simple method of describing that property of a radiation detector which is greater for the detector that achieves a greater signal-to-noise ratio on a given radiation signal. Both the concept and a name for the concept have been lacking heretofore. 'Detectivity' is suggested as the name for the concept, and the detectivity is defined as the reciprocal of the noise equivalent input of a detector.

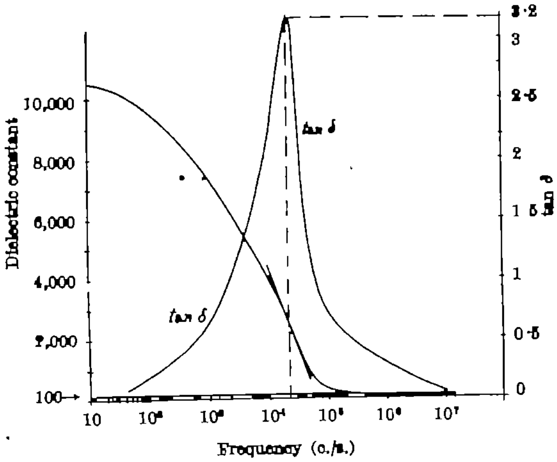
A New Dielectric Material

I HAVE prepared a ceramic material which, although apparently being pure rutile, has quite different dielectric properties. It was obtained by heating pure titanium oxide (TiO_2) to a temperature of 1,400° C., as described elsewhere[1]. X-ray analysis leads to the same Debye–Scherrer pattern as rutile (axis ratio 1 : 0·911). The frequency dependence of the dielectric constant and of tan θ (θ = loss angle) of this substance is shown in the accompanying graph, measured at the Centre d'études des Télécommunications, Paris, by courtesy of the director, M. Caye. This substance thus exhibits a Debye type of loss connected with a very high static dielectric constant.



L. NICOLINI

[1] Italian Patent 7592, Aug. 9, 1951.

Zoological Nomenclature

As from March 1, 1953, the International Commission on Zoological Nomenclature will start to vote on the following cases involving the possible use of its plenary powers for the purposes specified in brackets against each entry. Full particulars of these cases were published on August 29, 1952, in the *Bulletin of Zoological Nomenclature*, those relating to cases (1) to (4) in Part 10 and those relating to cases (5) to (14) in Part 11 of Vol. 6.

(1) *Sphinx* Linnæus, 1758 (Cl. Insecta, Ord. Lepidoptera) (designation of type species); (2) Houttuyn (M.H.), 1787, *Animalium Musei Houttuinensi Index* (suppression); (3) *Phalæna* Linnæus, 1758 (Cl. Insecta, Ord. Lepidoptera) (suppression, and validation as of generic status of eight terms used by Linnæus for groups thereof: *Bombyx*, *Noctua*, *Geometra*, *Tortrix*, *Pyralis*, *Tinea*, *Alucita*, as from 1758, *Attacus*, as from 1767; and names of families based thereon; alternatively, for *Bombyx* and *Pyralis* (as from Fabricius, 1775) (designation of type species); (4) *Episema* Ochsenheimer, 1816 (Cl. Insecta, Ord. Lepidoptera) (designation of type species, thereby also preserving *Diloba* Boisduval, 1840); (5) *cydippe* Linnæus, 1761, *Papilio*, and *adippe* Linnæus, 1767, *Papilio* (Cl. Insecta, Ord. Lepidoptera) (suppression, and validation of *adippe* Denis and Schiffermuller, 1775, *Papilio*); (6) *hispidus* Olivier, 1811, *Palæmon* (Cl. Crustacea, Ord. Decapoda) (validation); (7) *Sicyonia* Milne Edwards, 1830 (Cl. Crustacea, Ord. Decapoda) (validation); (8) *Hymenocera* Latreille, 1819 (Cl. Crustacea, Order Decapoda) (designation of type species); (9) *Pyramidella* Lamarck, 1799 (Cl. Gastropoda, Sub-Cl. Prosobranchia) (validation, by suppression of *Plotia* Roeding, 1798); (10) *Dasypeltis* Wagler, 1830 (Cl. Reptilia) (validation); (11) *Trichopsylla* Kolenati, 1863 (Cl. Insecta, Ord. Siphonaptera) (suppression); (12) *pungens* Walcknaer, 1802, *Pulex*, and *vespertilionis* Dugès, 1832, *Pulex* (Cl. Insecta, Ord. Siphonaptera) (suppression); (13) *sinus* Linnæus, 1767, *Coluber* (Cl. Reptilia) (determination of application); (14) *Mellita* Agassiz, 1841 (Cl. Echinoidea) (validation).

Comments on the above cases should be sent to me as soon as possible.

FRANCIS HEMMING
(Secretary to the International Commission on Zoological Nomenclature).

28 Park Village East,
Regent's Park,
London, N.W.1.
Aug. 29.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, December 1

Royal Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Anniversary Meeting.

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. G. de Q. Robin and Mr. J. J. Holtzscherer: "Depth of Polar Ice Caps".

Society of Engineers (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. B. R. Byrne: "The Fatigue of Metals—Facts and Theories Reviewed".

Society of Chemical Industry, London Section (joint meeting with the Fine Chemicals Group and the London and South-Eastern Counties Section of the Royal Institute of Chemistry, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. G. E. Smith: "Essential Oils".

Tuesday, December 2

School of Pharmacy, University of London (in the Meyerstein Lecture Theatre, Westminster Hospital Medical School, Horseferry Road, London, S.W.1), at 5.30 p.m.—Sir Eric Rideal, F.R.S.: "Adsorption and Reaction in Monolayers and some Biological Implications".*

Wednesday, December 3

Royal Sanitary Institute (at 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Discussion on "Investigations into Swimming Bath Water Treatment" (to be opened by Dr. S. G. Burgess, Mr. D. Burns and Mr. C. W. Tidy).

Physical Society, Colour Group (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 3.30 p.m.—Mr. Oliver Cox: "The Architectural Use of Colour in Schools".

Royal Society of Medicine, Surgery Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Discussion on "The Use of Radio-Isotopes in Surgery".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. D. A. Wright: "A Survey of Present Knowledge of Thermionic Emitters".

University of London (in the Senate House, Malet Street, London, W.C.1), at 5.30 p.m.—Prof. M. Born, F.R.S.: "Research in Theoretical Physics by the Department of Mathematical Physics, Edinburgh".* (Further Lectures on December 5 and 10.)

Society of Public Analysts and Other Analytical Chemists, Polarographic Discussion Panel of the Physical Methods Group (at Sir John Cass College, Jewry Street, London, E.C.3), at 6.30 p.m.—Annual General Meeting; Mr. P. R. D. Pomeroy and Mr. R. A. White: "Modification of the Cambridge Polarograph for Derivative Polarography"; Dr. W. Stross: "The Polarographic Determination of Cadmium in Aluminium and some other Alloys".

Society of Public Analysts and Other Analytical Chemists (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Dr. H. H. Green: "Industrial Fluorosis".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Scientific Films: "The Chameleon" (English), "Marvels in Miniature" (Australian), "L'Hippocampe" (French), "Cardiac Output in Man" (introduced by Prof. J. McMichael).

Wednesday, December 3—Friday, December 5

European Association of Exploration Geophysicists (at the Stadthalle, Corvinusplatz 2, Hanover, Germany).—Third Meeting.

Thursday, December 4

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. H. E. M. Barlow: "Guided Electric Waves".*

Physical Society, Low Temperature Group (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Annual General Meeting; at 5.30 p.m.—Prof. F. E. Simon, F.R.S.: "Has Low Temperature Physics any Practical Applications?"

British Institution of Radio Engineers, Scottish Section (in the Department of Natural Philosophy, The University, Edinburgh), at 7 p.m.—Mr. J. H. H. Merriman: "The London to Kirk o' Shotts Television Cable/Radio Link System".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Royal Society of Medicine, Neurology Section (at 1 Wimpole Street, London, W.1), at 8.15 p.m.—Dr. F. M. R. Walshe: "Thoughts on the Equation of Mind with Brain" (Hughlings Jackson Lecture).

University of London (in the Swanley Hall, Wye College, Wye, Kent), at 8.15 p.m.—Sir David Brunt, F.R.S.: "The Basis of Micro-climatology".*

Friday, December 5

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. W. J. Bray, Mr. R. L. Cooke and Mr. R. W. White: "The London-Wenvoe Experimental Radio Link for Television".

Society of Dyers and Colourists, London Section (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Dr. P. R. Peacock: "Food Dyes".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. F. J. Siddle: "New Fibres and the Problem of Colouring Them".

Society of Cosmetic Chemists of Great Britain (at the British Colour Council, 13 Portman Square, London, W.1).—Mr. Taylor: "Detergents".

Saturday, December 6

Hospital Physicists' Association (in the Reid-Knox Hall, British Institute of Radiology, 32 Welbeck Street, London, W.1), at 10 a.m.—Discussion on "Ionization Chambers and various Aspects of their Use in the Measurement of X-Rays and Gamma-Rays".

British Mycological Society (at the Linnean Society of London, Burlington House, Piccadilly, London, W.1), at 12 noon.—Annual General Meeting; at 2.30 p.m.—Discussion on "Micro-Structure in relation to the Identification of Higher Fungi".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. J. W. Brailsford: "The Mildenhall Treasure".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biochemist in the Department of Pathology—The Area Pathologist, Royal Devon and Exeter Hospital, Exeter (December 6).

Educational Psychologist at the Guildford Child Guidance Clinic—The County Medical Officer, County Hall, Kingston-upon-Thames (December 6).

Physicist (Senior Experimental Officer) to organize and supervise operations involving processing of active materials and to be responsible for accounting and movement control of active materials used by research and development group, and Physicists (Assistant Experimental Officers) to carry out radiation measurements with special reference to health hazards, at a Ministry of Supply establishment at Aldermaston—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.292/52A (December 6).

Radio-Biologist for the Radiotherapy Department, for research in radio-biology in connexion with radiation in general—The Secretary and House Governor, Mount Vernon Hospital, Northwood, Middx. (December 6).

Engineers at a Ministry of Supply establishment at Bickley, Kent.—Ref. C. 646/52A, for technical inspection of optical and survey instruments and allied equipment; Ref. C. 678/52A, for control of group engaged on above duties—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (December 13).

Experimental Officer at the National Physical Laboratory, Teddington, to assist in installation and running of large servo-connected differential analyser and design of other analogue computing equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.448/52A (December 13).

Scientists, Grade II, or Scientists, Grade III, or Scientific Technical Officers, Grade I (with degrees, or equivalent, in physics, chemistry, mathematics or mining engineering) on the staff of the Director of Scientific Control, to carry out environmental studies at collieries in connexion with a long-term field research into the occurrence and causes of pneumoconiosis—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting T1/568 (December 20).

Director of the Division of Industrial Hygiene, New South Wales Department of Public Health—The Agent General for New South Wales, 56 Strand, London, W.C.2 (January 12).

Chair of Geology and Mineralogy—The Secretary of the University Council, Trinity College, Dublin (January 15).

Reader in the Department of Soil Science and Chemistry, Imperial College of Tropical Agriculture, Trinidad—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2 (January 15).

Chair of Child Health in the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 31).

Lecturer in Aircraft Structures and Design—The Secretary of University Court, The University, Glasgow (January 31).

Agricultural Officer and a Biochemist in the Department of Agriculture, Fiji—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CSO.63/49/01–2.

Assistant (Grade A) in Physics—The Principal, Technical College, Queen Street South, Huddersfield.

Assistant Physicist (with honours degree in physics) in the Radiotherapy Centre—The Group Secretary, War Memorial Hospital, Scunthorpe, Lincs.

Assistant Research Chemist (organic) in the Hop Research Department—The Registrar, Wye College, Wye, Ashford, Kent.

Combustion Research Chemist, to conduct both research and investigation of practical problems in the combustion of gas turbine and jet engine fuels and to assume some responsibility in the guidance and supervision of this work—The Chief, Personnel Branch, National Research Council, Ottawa, Ont., Canada; or The Chief Scientific Liaison Officer, National Research Council, Africa House, Kingsway, London, W.C.2.

Educational Psychologist (female, with an honours degree in psychology) to the Child Guidance Clinic—The Town Clerk, Town Hall, Bradford.

Geologists (with a first- or good second-class honours degree in geology) in the combined Survey Department for Sarawak and North Borneo (C.S.D.60/92/01), and Geologists (with a first- or good second-class honours degree in geology) in the British Solomon Islands Protectorate (C.S.D.60/46/01)—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting the appropriate Ref. No.

INSPECTORS OF MINES (with a degree or diploma of a recognized School of Metalliferous Mining, and two years postgraduate experience) in Nigeria—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.99/14/01.

LECTURER (with honours degree in physiology) IN PHYSIOLOGY AND PHARMACOLOGY—The Registrar, Municipal College, Portsmouth.

LECTURER OR ASSISTANT LECTURER IN AERODYNAMICS—The Head of Aeronautics Department, Imperial College of Science and Technology, South Kensington, London, S.W.7.

MINING GEOLOGIST (with a B.Sc. degree with honours in mining geology) in Sierra Leone—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27079/40.

PHYSICIST OR ELECTRICAL ENGINEER at outstation of the Royal Aircraft Establishment, Woodbridge, Suffolk, to lead section engaged on application of radar to ballistics and other trials, including responsibility for conduct of trials, maintenance of ground radar equipment, plotting tables, etc., and development of techniques—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.291/52A.

PRINCIPAL SCIENTIFIC OFFICER at Sellafield, for work on health physics and other research problems associated with handling radioactive materials—The Ministry of Supply, Risley, Warrington, Lancs, quoting 393.

RESEARCH PLANNING OFFICERS at Salwick and Sellafield—The Ministry of Supply, Division of Atomic Energy (Production), Warrington, Lancs, quoting 385.

SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics, or equivalent, and an interest in properties of semi-conductors) at the Ministry of Supply Telecommunications Research Establishment, Malvern, for research into methods of sensitization of photo-conductive cells, particularly lead selenide—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.298/52A.

SCIENTIST, Grade II or III (graduate chemist), in the Cannock Chase area—The Divisional Establishment Officer, National Coal Board, West Midlands Division, Himley Hall, Dudley, Worcs.

SENIOR SCIENTIFIC OFFICER OR SCIENTIFIC OFFICER AT THE ROAD RESEARCH LABORATORY, West Drayton, for research on properties and performance of bituminous road materials and related machinery—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W 1, quoting E.506/52.

SELECTION AND TRAINING FOR RESEARCH

SINCE in its report on "University Development from 1935 to 1947" the University Grants Committee commented on "the tendency to over-emphasize in the name of research the value of certain forms of postgraduate activity which have little real importance from the point of view of advancing the frontiers of learning", the research activities of the universities of Great Britain have been frequently discussed, perhaps more especially in relation to higher technological education. In an interim report for the years 1947–51 issued early this year, the University Grants Committee reiterated the opinion that the universities must always remain the main agency for fundamental research, and from this view there is little, if any, dissent. The question at issue is rather the extent to which the ordinary science graduate should receive some training in research, and whether such training fits him or otherwise for an industrial career, which may or may not be in research.

It has been argued, though more particularly in respect of fundamental research, that only the exceptional man, who has given evidence of possessing the appropriate qualities of mind, should be encouraged to pursue postgraduate research in the university, and that such training is quite unnecessary for the ordinary student. If he has acquired a clear understanding of the scientific method and of the technique and fundamental principles of his chosen discipline, he should be able to adapt himself to whatever work may be required of him when he enters industry or on any other career. Moreover, the shortage of trained scientific men has made it essential that the methods of training, whether before or after entering industry or the selected occupation, should be as efficient as possible from the point of view of avoiding misfits and waste of trained man-power and of securing easy and smooth adaptation.

Such considerations make the proceedings of the second annual conference on industrial research held at Columbia University, in June 1951* of wide interest in Great Britain as well as in the United States of America. The conference, which was sponsored by the Department of Industrial Engineering of that University, was concerned specifically with the selection, training and use of personnel in industrial research. To some extent it strayed into side-issues, as, for example, the discussion on operational research provoked by Mr. R. L. Ackoff's paper on methodology and mathematical statistics and their application in research, and by the papers of Dr. P. N. Powers on industrial research workers and defence, and R. M. Hogan on research and national man-power policy. The latter papers, however, demonstrated that the question of efficiency and avoidance of waste in training is as important in the United States as it is in Britain, and Mr. Ackoff's contribution emphasized the importance of the issue between generalized and specialized training in regard to the assimilation of the graduate in industry.

---

* Selection, Training and Use of Personnel in Industrial Research. Proceedings of the Second Annual Conference on Industrial Research, June 1951. Sponsored by the Department of Industrial Engineering, Columbia University. David B. Hertz (editor), Albert H. Rubenstein (assistant editor). Pp. x+274. (New York: King's Crown Press; London. Oxford University Press, 1952.) 30s. net.

The two most critical issues raised in these discussions turn, first, on the specific qualities required in the industrial research worker, and second, on the recognition of these qualities and selection of the workers who possess them. The decision between general and specific training must depend, at least in part, on our ability to define fairly precisely the qualities for which we are looking, and to consider the methods which most effectively encourage the development of these qualities. Until that stage is achieved, there seems to be little point in fostering postgraduate research when the utility of the latter may be called in question from the point of view of subsequent adaptation of the graduate concerned.

In two of the papers, those of E. W. Engstrom, vice-president in charge of research in the Radio Corporation of America, and of Prof. D. B. Hertz, of Columbia University, much stress was laid upon the desirability of originality and creativeness. These are precisely the qualities that mark the outstandingly successful research worker, whether in industry or elsewhere, and at the same time they are those which are the most difficult to distinguish. Even as to the conditions in which they flourish and are best fostered we know relatively little, though those conditions are also the conditions in which research work in general is most fruitfully pursued, though not necessarily those in which high inventiveness is likewise encouraged.

Nothing in the discussion of these two papers suggested that, despite agreement as to the importance of creativeness, there is any recognized means of detecting it at an early stage; as Dr. Engstrom remarked, only experience can show whether a man possesses such powers. Apart from this, the main emphasis was laid on the soundness of the scientific training which a candidate for a research post in industry has received, and on his ability to work with others as a group. Whether he has already been engaged in research appears to be immaterial so long as he possesses these qualifications. It might be said that, as Dr. H. A. Leedy pointed out in a subsequent paper on training young research workers, the capacity to learn is more important than the knowledge the candidate has actually acquired, subject to a certain basic minimum.

It is comparatively easy to specify desirable qualifications for a research worker, as not only Dr. Leedy but also other conference speakers recognized, notably, besides Dr. Engstrom, Dr. H. K. Work in his paper on the university's role in training research workers. Besides fundamental professional knowledge already noted, and the ability to use it, much stress was laid by these three speakers on the personal qualities and character of the applicant, including not merely the ability to work with others, but also such qualities as the capacity to express himself clearly and concisely, his scientific inquisitiveness, practical outlook, initiative and energy. The difficulty is not to specify the desirable qualities but to determine which applicants possess them, and Dr. Leedy frankly admitted that the best we can hope for is that some few of the men chosen will live up to expectations.

Although it may be conceded that the quality of creativeness and imagination which lifts the research worker to the highest level is almost impossible to diagnose by any selection technique, Dr. Leedy's view as to the futility of selection techniques seems to be too pessimistic and scarcely warranted by the general trend of the discussions at this conference. At least if we know what we are looking for we should be able to eliminate a fair proportion of misfits, and even to do this involves avoiding waste of trained man-power on a scale sufficiently serious at present to justify an effort to improve existing techniques of selection. On this the Conference at Columbia University reflected opinion freely expressed at the Conference on Industry and the Universities organized by the Federation of British Industries in Great Britain in November 1949. Moreover, it brought out, as did the latter, that what industry looks for in its research workers is, in the first place, not so much training in the technique of research, or even the possession of creative ability and imagination. Industry is prepared to take a chance that the second will develop as training in the necessary research technique is given within industry itself. The prime necessity is the possession of a sound knowledge and understanding of some scientific discipline, and the ability to think clearly and to express ideas clearly in speech or writing. If a recruit possesses these qualities, together with those other personal qualities such as reliability and the capacity to co-operate, industry will be able to make effective use of him, even if he does not prove to be in the first rank as an original investigator. These qualities, moreover, are those which should be to a large extent the natural result of a university education, not only in the faculty of science but also in any other faculty. To the extent to which the university graduate seeking to enter industry is deficient in them, we should seek to inquire into the character of the education he received at his university and to remedy such deficiency at its source.

The corollary of an efficient selection technique for industrial research personnel is an appropriate standard in university and in technological education, and this is a point to be remembered in the current discussion on the expansion of higher technological education in Britain. There is, however, a further reason why industry can afford to take some chance in respect of creative ability on the part of its recruits for industrial research. Prof. S. B. Littauer, in his paper "What Makes a Good Research Man", pointed out, much as other speakers had done, that a research worker must possess a background of knowledge as well as some imagination and inventiveness, and that the extent to which these are desirable is not easy to define. In technical research, however, logical procedures are dominant factors: such research demands the astute organization of reproducible knowledge pertinent to the problem under study, the focusing and weighing of evidence, the determination of the relevance of data and the unbiased testing of hypotheses. These and other requirements, such as making inferences from observations about the general principles which govern these observations and predicting from accepted principles what may be expected to result from selected operational procedures, amount to a methodology, the adequacy of which largely determines the effectiveness of the investigation.

Prof. Littauer argues that the research recruit should not be expected to possess such a scientific methodology, but that its acquisition should be encouraged by the research organization and the research director. What ultimately makes a good research man is a research organization and a research director that provide such encouragement, and with it the atmosphere, opportunity and stimulation to expand and utilize efficiently his substantive knowledge in an organized attack on the research problems confronting him. Not only will an organization which provides such conditions get the most effective results from its existing staff, but also it will not need to worry about selecting the creative and outstanding research worker. Such men will be attracted to work in the conditions which are most favourable to creative thought and work.

Thus we come back to the conclusions of the Barlow report on scientific staff. Selection techniques have their part to play in avoiding misfits, and especially if they have been used still earlier to avoid wasting time and money on those unfitted to profit by a university training; but they are of secondary importance compared with the provision of conditions in which creative work is most fruitfully pursued. If we do not offer these conditions, we shall not attract men of the quality we desire; and the warning is one that should be kept specially in mind at such a time of stringent economy, not least in government research establishments. But it is also relevant to the question of the form which new technological institutions in Britain are to take. Whether the technological research on an increased scale which is so desirable in Great Britain is developed within the walls of university departments of technology or of the higher colleges of technology or of a new technological institution, or in co-operation with industry or research associations in industry itself, matters relatively little, provided the conditions of academic freedom and status are provided which will ensure that the institution attracts to its staff men of the right ability and standing. If such conditions are satisfied and the right atmosphere exists, even sponsored research itself may present little difficulty and may indeed encourage the development, not merely of ability and technique in research, but also of the inventiveness and scientific curiosity which are so desirable.

AN ESSAY ON MORPHOGENESIS

Morphogenesis

An Essay on Development. By John Tyler Bonner. Pp. vii+296. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1952.) 32*s*. 6*d*. net.

THE subject of morphogenesis can be approached from many different points of view. In this very readable 'essay' Dr. Bonner has drawn widely on both the plant and animal kingdoms, especially the lower groups, to illustrate particular points. In general, his subject-matter will be familiar to those whose special interest lies in the study of morphogenesis; but he has dealt with many aspects in a new and refreshing manner. Thus he has contributed chapters on size and pattern, physics and chemistry of development, patterns of growth, patterns of morphogenetic movements, polarity and symmetry, patterns of differentiation, and an analysis of development. Botanists in particular will be interested to note to what good use he has put the developmental data of green algæ (Volvocales and Chlorococcales), myxomycetes and oomycetous fungi, in discussing morphogenetic movements which are so familiar to the zoologist. The author regards morphogenesis, or the emergence of an organismal pattern, as being referable essentially to the progressive, constructive processes of growth, morphogenetic movement and differentiation; and to the limiting of these processes in various ways by intrinsic and extrinsic factors which check, guide and canalize them. He also recognizes that the physical bases of many morphogenetic processes may or may not be the same for all organisms. Polarity, for example, has a different physical basis in different organisms.

In that even the simplest morphological or structural feature is the result of the action of a whole nexus of factors, and these of different kinds, it may well be doubted if any morphogenetic development will ever be adequately explained. Dr. Bonner, of course, makes no claim to having solved any of the problems of morphogenesis; but in a lucid and interesting manner he has discussed many of the major aspects and has shown, by reference to a wide range of examples of individual developments, that some phenomena are of very general occurrence and hence that it is reasonable to seek for common underlying causes.

The data of morphogenesis, already multitudinous, are increasing daily from diverse sources. There may, therefore, be several views as to how the subject is to be tackled in the hope of advancing knowledge. Few will disagree with the author that "the only way of finding a solution to the riddle of development will be to discover new and penetrating facts". As to how these facts are to be discovered it is, of course, hard to be explicit; but the thesis is advanced that a sustaining aim should be to search for a micro-theory which would explain in a satisfying manner the general phenomena of development; for such a theory is more likely to afford an insight into the inner mechanism of the relevant phenomena than any other kind of theory. The same general idea has also been advanced by other investigators, for example, Woodger. This matter is argued closely by the author, and, as he points out, such a micro-theory does not necessarily imply that all the phenomena of biology are to be brought down to physics and chemistry: some kind of intermediate micro-theory may prove quite satisfactory—for example, the action of genes as envisaged in contemporary genic theory. No micro-theory can yet be offered ; but the kind that would be satisfying would be one in which, as in crystal structure, the organism could be envisaged as being constructed of small repetitive units.
